(57) **ABSTRACT**

Semiconductor structures include an active region between a plurality of layers of InGaN. The active region may be at least substantially comprised by InGaN. The plurality of layers of InGaN include at least one well layer, and at least one barrier layer proximate the at least one well layer. Methods of forming semiconductor structures include growing such layers of InGaN to form an active region of a light emitting device, such as an LED. Luminary devices include such LEDs.

This application is a continuation of U.S. patent application Ser. No. 14/211,403, filed Mar. 14, 2014, now U.S. Pat. No. 9,117,955, issued Aug. 25, 2015, which claims the benefit of U.S. Provisional Patent Application Ser. No. 61/789,792, filed Mar. 15, 2013, the disclosure of each of which is hereby incorporated herein in its entirety by this reference. The subject matter of this application is also related to the subject matter of U.S. patent application Ser. No. 14/211,590, filed Mar. 14, 2014, now U.S. Pat. No. 9,246,057, issued Jan. 26, 2016 which claims the benefit of U.S. Provisional Patent Application Ser. No. 61/790,085, filed Mar. 15, 2013, in the name of Arena et al.; and U.S. patent application Ser. No. 14/211,844, filed Mar. 14, 2014, which claims the benefit of U.S. Provisional Patent Application Ser. No. 61/788,441, filed Mar. 15, 2013, in the name of Debray et al.; the disclosures of each of which are incorporated herein in its entirety by this reference.

TECHNICAL FIELD

The present disclosure relates to semiconductor structures and light emitting devices fabricated from such semiconductor structures that have an active region comprising InGa_N, to methods of fabricating such light emitting devices, and to devices that include such light emitting devices.

BACKGROUND

Light emitting devices such as light emitting diodes (LEDs) are electrical devices that emit electromagnetic radiation in the form of visible light when a voltage is applied across an active region of the LED between an anode and a cathode. LEDs typically comprise one or more layers of semiconductor material, within which electrons supplied from the anode and holes supplied from the cathode recombine. As the electrons and holes recombine within the active region of the LED, energy is released in the form of photons, which are emitted from the active region of the LED.

LEDs may be fabricated to include a wide range of different types of semiconductor materials including, for example, III-V semiconductor materials, and II-V semiconductor materials. The wavelength of the light emitted from any particular LED is a function of the amount of energy released when an electron and a hole recombine. Thus, the wavelength of the light emitted from the LED is a function of relative difference in energy between the energy level of the electron and the energy level of the hole. The energy levels of the electrons and the energy levels of the holes are at least partially a function of the composition of semiconductor materials, the doping type and concentration, the configuration (i.e., crystal structure and orientation) of the semiconductor materials, and the quality of the semiconductor materials within which recombination of the electrons and holes occurs. Thus, the wavelength of the light emitted from an

2

LED may be selectively tailored by selectively tailoring the composition and configuration of the semiconductor materials within the LED.

In is known in the art to fabricate LEDs that comprise III-V semiconductor materials, such as Group III nitride materials. Such Group III nitride LEDs are known to be capable of emitting radiation in the blue and green visible regions of the electromagnetic radiation spectrum, and are known to be capable of operating at relatively high power and luminosity.

BRIEF SUMMARY

This summary is provided to introduce a selection of concepts in a simplified form. These concepts are described in further detail in the detailed description of example embodiments of the disclosure below. This summary is not intended to identify key features or essential features of the claimed subject matter, nor is it intended to be used to limit the scope of the claimed subject matter.

In some embodiments, the present disclosure includes a semiconductor structure comprising a GaN base layer having a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms. An active region is disposed over the base layer, and the active region comprises a plurality of layers of InGa_N. The plurality of layers of InGa_N include at least one In_wGa_{1-w}N well layer, wherein $0.10 \leq w \leq 0.40$, and at least one In_bGa_{1-b}N barrier layer, wherein $0.01 \leq b \leq 0.10$. An electron blocking layer is disposed on a side of the active region opposite the GaN base layer. A p-type bulk layer is disposed on the electron blocking layer, and the p-type bulk layer comprises In_pGa_{1-p}N, wherein $0.01 \leq p \leq 0.08$. A p-type contact layer is disposed on the p-type bulk layer, and the p-type contact layer comprises In_cGa_{1-c}N, wherein $0.00 \leq c \leq 0.10$.

In additional embodiments, the disclosure includes light emitting devices fabricated from such semiconductor structures. For example, in additional embodiments, the present disclosure includes a light emitting device comprising a GaN base layer having a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms. An active region is disposed over the base layer. The active region comprises a plurality of layers of InGa_N, and the plurality of layers of InGa_N include at least one well layer and at least one barrier layer. An electron blocking layer is disposed over the active region. A p-type In_pGa_{1-p}N bulk layer is disposed over the electron blocking layer, and a p-type In_cGa_{1-c}N contact layer disposed over the p-type In_pGa_{1-p}N bulk layer. Additionally, a critical strain energy of the light emitting device may be about 4500 (a.u.) or less.

Additional embodiments of the disclosure include methods of making such structures and devices. For example, in some embodiments, the present disclosure includes a method of forming a semiconductor structure in which a GaN base layer is provided that has a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Å. A plurality of layers of InGa_N is grown to form an active region over the base layer. Growth of the plurality of layers of InGa_N includes growing at least one well layer comprising In_wGa_{1-w}N, wherein $0.10 \leq w \leq 0.40$, and growing at least one barrier layer over the at least one well layer, the at least one barrier layer comprising In_bGa_{1-b}N, wherein $0.01 \leq b \leq 0.10$. An electron blocking layer is grown over the active region. A p-type In_pGa_{1-p}N bulk layer is grown over the electron blocking layer, wherein $0.01 \leq p \leq 0.08$, and a p-type In_cGa_{1-c}N contact layer is grown over the p-type In_pGa_{1-p}N bulk layer, wherein $0.00 \leq c \leq 0.10$.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a simplified side view of a semiconductor structure that includes one or more InGaN well layers and one or more InGaN barrier layers in an active region of the semiconductor structure in accordance with embodiments of the present disclosure.

FIG. 1B is a simplified diagram illustrating the relative differences in the energy level of the conduction band in an energy band diagram for the different materials in the various layers of the semiconductor structure of FIG. 1A.

FIG. 2A is a simplified side view of another semiconductor structure similar to the semiconductor structure of FIG. 1A, but further including an electron stopping layer between an active region and a base layer of the semiconductor structure.

FIG. 2B is a simplified conduction band diagram for the semiconductor structure of FIG. 2A.

FIG. 3A is a simplified side view of another semiconductor structure similar to the semiconductor structure of FIG. 1A, but further including a strain relief layer between an active region and a base layer of the semiconductor structure.

FIG. 3B is a simplified conduction band diagram for the semiconductor structure of FIG. 3A.

FIG. 4A is a simplified side view of another semiconductor structure similar to the semiconductor structure of FIG. 1A, but further including additional thin GaN barrier layers within the active region of the semiconductor structure.

FIG. 4B is a simplified conduction band diagram for the semiconductor structure of FIG. 4A.

FIG. 5A is a simplified side view of another semiconductor structure similar to the semiconductor structure of FIG. 1A, but further including a well overflow structure within the active region of the semiconductor structure.

FIG. 5B is a simplified band diagram for the semiconductor structure of FIG. 5A.

FIG. 6A is a simplified top plan view of an intermediate semiconductor structure that may be employed to fabricate a growth template utilized for fabrication of semiconductor structures in accordance with embodiments of methods of the present disclosure.

FIG. 6B is a partial cross-sectional side view of the intermediate semiconductor structure of FIG. 6A.

FIG. 6C is a partial cross-sectional side view of a growth template that may be employed to fabricate semiconductor structures in accordance with embodiments of methods of the present disclosure.

FIG. 6D illustrates layers of a growth stack epitaxially deposited on a growth template like that of FIG. 6C.

FIG. 7 is a partial cross-sectional side view of a light emitting device fabricated from semiconductor structures in accordance with embodiments of methods of the present disclosure.

FIG. 8 is a partial cross-sectional side view of an additional light emitting device fabricated from semiconductor structures in accordance with embodiments of methods of the present disclosure.

FIG. 9 is a graph illustrating the relationship between internal quantum efficiency and the total strain energy of semiconductor structures formed in accordance with embodiments of methods of the present disclosure.

FIG. 10A is a simplified side view of a previously known LED that includes InGaN well layers and GaN barrier layers in an active region of the LED.

FIG. 10B is a simplified conduction band diagram for the LED of FIG. 10A.

FIG. 11A is a graph illustrating calculated band edges for the conduction band and the valence band with zero applied

voltage across the active region of the LED of FIG. 10A, the calculations obtained using a computational model of the LED.

FIG. 11B is a graph similar to that of FIG. 11A, but illustrating the calculated band edges for the conduction band and the valence band with a current density of 125 A/cm² flowing across the active region of the LED due to an applied voltage across the active region.

FIG. 11C is a graph illustrating the calculated intensity of emitted radiation as a function of wavelength for each InGaN quantum well layer in the LED of FIG. 11A.

FIG. 11D is a graph illustrating the calculated carrier injection efficiency as a function of applied current density across the active region of the LED of FIG. 11A.

FIG. 11E is a graph illustrating the calculated internal quantum efficiency as a function of applied current density across the active region of the LED of FIG. 11A.

FIG. 12A is a simplified side view of an LED of the present disclosure, which is similar to that of FIG. 1A and includes InGaN well layers and InGaN barrier layers in an active region of the LED.

FIG. 12B is a simplified conduction band diagram for the LED of FIG. 12A.

FIG. 13A is a graph illustrating calculated band edges for the conduction band and the valence band with zero applied voltage across the active region of the LED of FIG. 12A, the calculations obtained using a computational model of the LED.

FIG. 13B is a graph similar to that of FIG. 13A, but illustrating the calculated band edges for the conduction band and the valence band with a current density of 125 A/cm² flowing across the active region of the LED due to an applied voltage across the active region.

FIG. 13C is a graph illustrating the calculated intensity of emitted radiation as a function of wavelength for each InGaN quantum well layer in the LED of FIG. 13A.

FIG. 13D is a graph illustrating the calculated carrier injection efficiency as a function of applied current density across the active region of the LED of FIG. 13A.

FIG. 13E is a graph illustrating the calculated internal quantum efficiency as a function of applied current density across the active region of the LED of FIG. 13A.

FIG. 14 illustrates an example of a luminary device that includes an LED of the present disclosure.

DETAILED DESCRIPTION

The illustrations presented herein are not meant to be actual views of any particular semiconductor material, structure, or device, but are merely idealized representations that are used to describe embodiments of the disclosure.

FIG. 1A illustrates an embodiment of a semiconductor structure **100**. The semiconductor structure **100** comprises a plurality of Group III nitride layers (e.g., indium nitride, gallium nitride, aluminum nitride and their alloys) and includes a base layer **102**, a p-type contact layer **104** and an active region **106** disposed between the base layer **102** and the p-type contact layer **104**, the active region **106** comprising a plurality of layers of InGaN. In addition, the active region **106** comprises at least one InGaN well layer and at least one InGaN barrier layer. In some embodiments, the active region **106** may be at least substantially comprised by InGaN (but for the presence of dopants). The semiconductor structure **100** further comprises an electron blocking layer **108** disposed over the active region **106**, a p-type bulk layer **110** disposed over the electron blocking layer **108** and a p-type contact layer **104** disposed over p-type bulk layer **110**.

The base layer **102** may comprise a GaN base layer **112**, wherein a growth plane of the GaN base layer **112** is a polar plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms. A light emitting device, such as a light emitting diode may be fabricated from the semiconductor structure **100**, as described in detail subsequently herein. However, in brief, a first electrode contact may be formed over a portion of the GaN base layer **112** and a second electrode contact may be formed over a portion of the p-type contact layer **104**, such that an electrical voltage may be supplied between the electrode contacts across the active region **106** thereby causing electromagnetic radiation (e.g., visible light) to be emitted from a light emitting device fabricated from the semiconductor structure **100**.

Embodiments of semiconductor structures of the present disclosure, which include an active region including at least one InGa_N well layer and at least one InGa_N barrier layer, may be fabricated using various types of methods for growing or otherwise forming Group III nitride layers such as InGa_N. As non-limiting examples, the various Group III nitride layers may be grown or otherwise deposited using one or more of a chemical vapor deposition (CVD) process, a metalorganic chemical vapor deposition process (MOCVD), a vapor phase epitaxy (VPE) process, an atomic layer deposition (ALD) process, a hydride vapor phase epitaxy (HVPE) process, a molecular beam epitaxy (MBE) process, an atomic layer deposition (ALD) process, a chemical beam epitaxy (CBE) process, etc.

In some embodiments, methods as disclosed in one or all of U.S. Patent Application Publication No. US 2010/0176490 A1, which published Jul. 15, 2010, now U.S. Pat. No. 8,486,771, issued Jul. 16, 2013, in the name of Letertre et al., U.S. Patent Application Publication No. US 2010/0109126, which published May 6, 2010, now U.S. Pat. No. 8,278,193, issued Oct. 2, 2012, in the name of Arena, U.S. Patent Application Publication No. US 2012/0211870, which published August 23, 2012, now U.S. Pat. No. 8,975,165, issued Mar. 0, 2015, in the name of Figuet and U.S. Patent Application Publication No. US 2012/0225539, which published Sep. 6, 2012, now U.S. Pat. No. 8,329,571, issued Dec. 11, 2012, in the name of Figuet, the disclosures of each of which application are hereby incorporated herein in their entirety by this reference, may be used to grow or otherwise deposit the various layers of Group III nitride. Such methods may enable the fabrication of group III nitride layers, such as InGa_N layers (and other optional Group III nitride layers) having compositions and thicknesses as described hereinbelow. Such methods may be utilized to form a growth template **113** upon which subsequent Group III nitride layers may be formed.

An example of such a method that may be used to fabricate the growth template **113** according to embodiments of the disclosure is briefly described below with reference to FIGS. 6A through 6C.

FIG. 6A is a top plan view of an intermediate semiconductor structure **650** utilized in the formation of growth template **113** (of FIG. 1A) on which one or more semiconductor structures and subsequent light emitting devices of the present disclosure may be fabricated, and

FIG. 6B is a simplified cross-sectional view of a portion of the intermediate semiconductor structure **650** utilized in the formation of the growth template **113**. The growth template **113** may be fabricated as disclosed in the aforementioned U.S. Patent Application Publication No. US 2010/0176490 A1, now U.S. Pat. No. 8,486,771, issued Jul. 16, 2013, and/or U.S. Patent Application Publication No. US 2010/0109126, now U.S. Pat. No. 8,278,193, issued Oct. 2, 2012. As disclosed therein, the intermediate semiconductor structure **650**

may include a sacrificial substrate **652**, a layer of compliant material **654** disposed on the sacrificial substrate **652**, and one or more In₃Ga₁₋₃N seed layers **656** each comprising a layer of Group III nitride material that is disposed over the compliant material **654**. The one or more In₃Ga₁₋₃N seed layers **656** may be used as a "seed" on which the various subsequent layers of the semiconductor structure **100** described herein may be formed.

The initial In₃Ga₁₋₃N seed layer may be formed on an initial growth substrate and subsequently transferred to sacrificial substrate **652** utilizing methods such as ion implantation, bonding and subsequent separation of a portion of the initial In₃Ga₁₋₃N seed layer (not shown). The initial growth substrate may comprise a growth substrate that is characterized in having a growth plane lattice mismatch with the initial In₃Ga₁₋₃N seed layer such that the In₃Ga₁₋₃N seed layer is formed in a strained manner. For example, the initial growth substrate may comprise a sapphire substrate including a gallium polar GaN seed layer, such that the In₃Ga₁₋₃N seed layer formed comprises a gallium polar In₃Ga₁₋₃N seed layer that is subjected to tensile strain.

The initial In₃Ga₁₋₃N seed layer may be formed or grown such that the In₃Ga₁₋₃N seed layer comprises a growth plane that comprises a polar plane of the Group III-nitrides. For example, the growth plane may be formed such that the In₃Ga₁₋₃N seed layer comprises a Gallium-polar plane. In addition, the initial In₃Ga₁₋₃N seed layer may be grown or otherwise formed such that the composition of the In₃Ga₁₋₃N seed layer is such that $0.02 \leq x \leq 0.05$. As one particular non-limiting example, the value of x in the In₃Ga₁₋₃N seed layer may be equal to about 0.03. The In₃Ga₁₋₃N seed layer also may be grown or otherwise formed to a thickness of greater than about two hundred nanometers (200 nm). The In₃Ga₁₋₃N seed layer, however, is formed in such a manner that the In₃Ga₁₋₃N seed layer does not surpass the In₃Ga₁₋₃N seed layer critical thickness, which is the thickness at which the strain in the In₃Ga₁₋₃N seed layer may relax by the formation of additional defects. This phenomenon is commonly referred to in the art as phase separation. Therefore the In₃Ga₁₋₃N seed layer may comprise a strained, high quality seed material.

By way of example and not limitation, the process known in the industry as the SMARTCUT® process may be used to transfer the In₃Ga₁₋₃N seed layer **656** to the sacrificial substrate **652** utilizing the layer of compliant material **654** as a bonding layer. Such processes are described in detail in, for example, U.S. Pat. No. RE39,484 to Bruel, U.S. Pat. No. 6,303,468 to Aspar et al., U.S. Pat. No. 6,335,258 to Aspar et al., U.S. Pat. No. 6,756,286 to Moriceau et al., U.S. Pat. No. 6,809,044 to Aspar et al., and U.S. Pat. No. 6,946,365 to Aspar et al., the disclosures of each of which are incorporated herein in their entirety by this reference.

The sacrificial substrate **652** may comprise a homogenous material or a heterogeneous (i.e., composite) material. By way of non-limiting examples, the support substrate **652** may comprise sapphire, silicon, Group III-arsenides, quartz (SiO₂), fused silica (SiO₂) glass, a glass-ceramic composite material (such as, for example, that sold by Schott North America, Inc. of Duryea, Pa. under the trademark ZERO-DUR®), a fused silica glass composite material (such as, for example, SiO₂—TiO₂ or Cu₂—Al₂O₃—SiO₂), aluminum nitride (AlN), or silicon carbide (SiC).

The layer of compliant material **654** may comprise, for example, a material having a glass transition temperature (T_g) of less than or equal to about 800° C. The layer of compliant material **654** may have a thickness in a range extending from about 0.1 μm to about 10 μm and, more particularly, about 1 μm to about 5 μm. By way of non-limiting example, the layer

of compliant material **654** may comprise at least one of an oxide, a phosphosilicate glass (PSG), borosilicate (BSG), a borophosphosilicate glass (BPSG), a polyimide, a doped or undoped quasi-inorganic siloxane spin-on-glass (SOG), an inorganic spin-on-glass (i.e., methyl-, ethyl-, phenyl-, or butyl), and a doped or undoped silicate.

The layer of compliant material **654** may be heated using, for example, an oven, furnace, or deposition reactor, to a temperature sufficient to decrease a viscosity of the layer of compliant material **654** to reflow the layer of compliant material **654** causing the one or more $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layers **656** to at least partially relax the crystal lattice strain. By decreasing the viscosity of the layer of compliant material **654**, the tensile strain in the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may be at least partially relaxed or may even be eliminated, thereby forming an $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** that comprises a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms.

Therefore, by relaxing at least a portion of the lattice strain within the $\text{In}_x\text{Ga}_{1-x}\text{N}$, a growth plane lattice parameter may be attained of greater than or equal to about 3.189 Angstroms in the $\text{In}_x\text{Ga}_{1-x}\text{N}$. A growth plane lattice parameter of greater than or equal to 3.189 Angstroms may correspond to the equilibrium growth plane lattice constant for wurtzite GaN. Therefore, in accordance with some embodiments of the disclosure, one or more GaN layers formed upon or over the $\text{In}_x\text{Ga}_{1-x}\text{N}$ layers of the present disclosure may be formed in a strain free state, i.e., substantially free of lattice strain.

Upon at least partial relaxation of the one or more $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layers **656**, the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layers **656** may be transferred to a support substrate, and subsequently the compliant material **654** and sacrificial substrate **652** may be removed to form the growth template **113** as illustrated in FIG. 1A and FIG. 6C. In greater detail and with reference to FIG. 6B and FIG. 6C, the at least partially relaxed $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may be attached to a support substrate **658**, and the sacrificial substrate **652** and compliant material **654** may be removed utilizing methods such as one or more of laser lift-off, wet etching, dry etching, and chemical mechanical polishing.

The support substrate **658** may comprise a homogenous material or a heterogeneous (i.e., composite) material. By way of non-limiting examples, the support substrate **658** may comprise sapphire, silicon, Group III-arsenides, quartz (SiO_2), fused silica (SiO_2) glass, a glass-ceramic composite material (such as, for example, that sold by Schott North America, Inc. of Duryea, Pa. under the trademark ZERO-DUR®), a fused silica glass composite material (such as, for example, $\text{SiO}_2\text{—TiO}_2$ or $\text{Cu}_2\text{—Al}_2\text{O}_3\text{—SiO}_2$), aluminum nitride (AlN), or silicon carbide (SiC).

As shown in FIG. 6C, in some embodiments, the growth template **113** may optionally include a layer of dielectric material **660** overlying a support substrate **658**. The layer of dielectric material **660** may, optionally, be formed over a major surface of the support substrate **658** or the one or more $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layers **656**, wherein the dielectric material **660** it utilized as a bonding layer to facilitate the bonding of the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** to the support substrate **658**. The layer of dielectric material **660** may include, for example, silicon oxynitride (SiON), silicon nitride (Si_3N_4), or silicon dioxide (SiO_2), and may be formed using, for example, chemical vapor deposition (CVD), physical vapor deposition (PVD), or atomic layer deposition (ALD). Therefore, the growth template **113**, as shown in FIG. 1A and FIG. 6C, comprises a support substrate **658** and an $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** disposed on the support substrate **658**.

In addition, the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may be formed over support substrate **658** such that the composition of the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may range from $0.02 \leq x \leq 0.05$. As one particular non-limiting example, the value of x in the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may be equal to about 0.03. Moreover, the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** may have a polar growth plane **662** comprising a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms. The $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer may also be formed to a total layer thickness T_s of greater than about one hundred nanometers (100 nm).

The growth template **113** forms a portion of the base layer **102** of FIG. 1A. The base layer may, in some embodiments, also include a GaN base layer **112**, wherein the GaN base layer inherits the crystal properties of the adjacent $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656**. Therefore the GaN base layer **112** may also comprise a polar growth plane, for example a gallium polar growth plane, with a growth plane lattice parameter of greater than or equal to about 3.189 Angstrom.

The GaN base layer **112** may at least substantially comprise of GaN (but for the presence of dopants). The GaN base layer **112** may have an average layer thickness T_n of between about ten nanometers (10 nm) and about three thousand nanometers (3,000 nm), or, in some embodiments, between about ten nanometers (10 nm) and about one thousand nanometers (1,000 nm). Optionally, the GaN base layer **112** may be doped. For example, the GaN base layer **112** may be doped n-type by doping with elements that are electron donors, such as silicon or germanium. The concentration of dopants in the GaN base layer **112** may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{20} \text{ cm}^{-3}$, or, in some embodiments, from about $5 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{19} \text{ cm}^{-3}$.

A first electrode contact may be formed on a portion of the GaN base layer **112** after forming one or more of the other various layers of the semiconductor structure **100** comprising InGaN to fabricate a light emitting device from semiconductor structure **100**.

The completed base layer **102**, as shown in FIG. 1A, comprises the growth template **113**, as described herein above, and the GaN base layer **112**. The various Group III nitride layers of the semiconductor structure **100** may be grown or otherwise formed in a layer-by-layer process as described in further detail subsequently herein. In some embodiments, the base layer **102** may comprise a base on which the other layers of the semiconductor structure **100** may be grown or otherwise formed. Thus, the various Group III nitride layers of the semiconductor structure **100** may be grown or otherwise formed sequentially beginning with the base layer **102** and moving in the direction from left to right from the perspective of FIG. 1A, although the structure may actually be oriented such that the base layer **102** is disposed on the bottom during fabrication. In other words, the structure may be oriented ninety degrees counter-clockwise from the orientation of FIG. 1A during fabrication.

As discussed in further detail below, the active region **106** is disposed between the base layer **102** and the p-type contact layer **104**. The active region **106** comprises at least one InGaN well layer **114** and at least one InGaN barrier layer **116**. In some embodiments, the active region **106** may be at least substantially comprised by InGaN (but for the presence of dopants). In particular, the active region **106** may comprise at least one well layer **114** comprising $\text{In}_w\text{Ga}_{1-w}\text{N}$, wherein $0.10 \leq w \leq 0.40$, or in some embodiments, wherein $0.12 \leq w \leq 0.25$, or in further embodiments wherein w is equal to about 0.14. The active region **106** also comprises at least one barrier layer **116** comprising $\text{In}_b\text{Ga}_{1-b}\text{N}$, wherein $0.01 \leq b \leq 0.10$ or in some embodiments wherein $0.03 \leq b \leq 0.08$,

or in further embodiments, wherein b is equal to about 0.05. In some embodiments, the InGaN barrier layer **116** may be proximate (e.g., directly adjacent) the at least one InGaN well layer **114**.

The active region **106** of the semiconductor structure is the region of the semiconductor structure, when fabricated into a light emitting device such as a light emitting diode (LED), in which electrons and holes recombine with one another to generate photons, which are emitted from the LED. In some embodiments, the photons are emitted in the form of visible light. At least some of the visible light may have a wavelength or wavelengths within the range of the electromagnetic radiation spectrum extending from about three hundred eighty nanometers (380 nm) to about five hundred sixty nanometers (560 nm).

As previously mentioned, the active region **106** of the semiconductor structure **100** comprises one or more InGaN well layers **114** and one or more InGaN barrier layers **116**, and may be at least substantially comprised by InGaN (but for the presence of dopants) in some embodiments. Thus, the active region **106** may consist essentially of InGaN in some embodiments. The active region **106** comprises one or more pairs of adjacent layers that include one well layer **114** and one barrier layer **116**, wherein each well layer **114** comprises $\text{In}_w\text{Ga}_{1-w}\text{N}$, in which $0.10 \leq w \leq 0.40$, and wherein each barrier layer **116** comprises $\text{In}_b\text{Ga}_{1-b}\text{N}$, in which $0.01 \leq b \leq 0.10$.

In the embodiment illustrated in FIGS. 1A and 1B, the active region **106** of the semiconductor structure **100** includes one (1) pair of active layers (a well layer **114** and a barrier layer **116**), although in additional embodiments, the active region **106** of the semiconductor structure **100** may include more than one pair of active layers. For example, the active region **106** of the semiconductor structure **100** may include from one (1) to twenty five (25) adjacent pairs of active layers, each pair including a well layer **114** and a barrier layer **116**, such that the active region **106** includes a stack of alternating well layers **114** and barrier layers **116** (in embodiments including more than one pair). It is understood however, that the number of barrier layers **116** may not be equal to the number of well layers **114**. The well layers **114** may be separated from one another by the barrier layers **116**. Thus, the number of barrier layers **116** may be equal to, one more than, or one less than, the number of well layers **114** in some embodiments.

With continued reference to FIG. 1A, each well layer **114** may have an average layer thickness T_w of between about one nanometer (1 nm) and about one thousand nanometers (1,000 nm), between about one nanometer (1 nm) and about one hundred nanometers (100 nm), or even between about one nanometers (1 nm) and about ten nanometers (10 nm). The well layers **114** may comprise quantum wells in some embodiments. In such embodiments, each well layer **114** may have an average layer thickness T_w of about ten nanometers (10 nm) or less. In other embodiments, the well layers **114** may not comprise quantum wells, and each well layer **114** may have an average layer thickness T_w greater than about ten nanometers (10 nm). In such embodiments, the active region **106** may comprise what are referred to in the art as "double heterostructures." Each barrier layer **116** may have an average layer thickness T_b of between about one nanometer (1 nm) and about fifty (50 nm), or even between about one nanometers (1 nm) and about ten nanometers (10 nm), although the barrier layers **116** may be thicker in other embodiments.

One or both of the well layers **114** and the barrier layers **116** may be doped. For example, one or both of the well layers **114** and the barrier layers **116** may be doped n-type by doping with elements that are electron donors, such as silicon or

germanium. The concentration of dopants in the well layers **114** may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{19} \text{ cm}^{-3}$, or may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $5 \times 10^{17} \text{ cm}^{-3}$ in some embodiments. Similarly, the concentration of dopants in the barrier layers **116** may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{19} \text{ cm}^{-3}$, or may range from about $1 \times 10^{18} \text{ cm}^{-3}$ to about $3 \times 10^{18} \text{ cm}^{-3}$ in some embodiments.

One or both of the well layers **114** and the barrier layers **116** may have a Wurtzite crystal structure. Additionally, in some embodiments, one or both of the well layers **114** and the barrier layers **116** may comprise a polar growth surface, such as a gallium polar growth surface, which may have an average lattice constant in the growth plane parallel to the interface or interfaces between the well layers **114** and the barrier layers **116** that is greater than or equal to about 3.189 Angstroms. More specifically, in some embodiments, the average growth plane lattice constant c may be between about 3.189 Angstroms and about 3.2 Angstroms.

The active region **106**, comprising at least one well layer and at least one barrier layer may have an average total thickness ranging between about forty nanometers (40 nm) and about one thousand nanometers (1000 nm), ranging between about forty nanometers (40 nm) and about seven hundred fifty nanometers (750 nm), or even ranging between about forty nanometers (40 nm) and about two hundred nanometers (200 nm).

With continued reference to FIG. 1A, the semiconductor structure **100** optionally may include additional layers between the active region **106** and the p-type contact layer **104**, and/or between the active region **106** and the base layer **102**. For example, in some embodiments, the semiconductor structure **100** may comprise a spacer layer **118** between the active region **106** and the base layer **102**.

The optional spacer layer **118** may comprise a layer of $\text{In}_{sp}\text{Ga}_{1-sp}\text{N}$, wherein $0.01 \leq sp \leq 0.10$, or wherein $0.03 \leq sp \leq 0.06$, or wherein sp is equal to about 0.05. The spacer layer **118** may be used to provide a more gradual transition between the base layer **102** and the layers of the active region **106**, which may have a different composition (and, hence, lattice parameter) relative to the GaN base layer **112**. Thus, the $\text{In}_{sp}\text{Ga}_{1-sp}\text{N}$ spacer layer **118** may be disposed directly between the base layer **102** and the active region **106** in some embodiments. By providing a more gradual transition between the base layer **102** and the active region **106**, stresses within the crystal lattice of the various layers of InGaN, and, hence, defects that may result from such stresses, may be reduced. The $\text{In}_{sp}\text{Ga}_{1-sp}\text{N}$ spacer layer **118** may have an average layer thickness T_{sp} of between about one nanometer (1 nm) and about one hundred nanometers (100 nm), or between about one nanometer (1 nm) and about one hundred nanometers (25 nm). As one particular non-limiting example, the average layer thickness T_{sp} may be equal to about ten nanometers (10 nm).

Optionally, the $\text{In}_{sp}\text{Ga}_{1-sp}\text{N}$ spacer layer **118** may be doped. For example, the $\text{In}_{sp}\text{Ga}_{1-sp}\text{N}$ spacer layer **118** may be doped n-type by doping with elements that are electron donors, such as silicon or germanium. The concentration of dopants in the spacer layer **118** may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{19} \text{ cm}^{-3}$. As one particular non-limiting example, the concentration of dopants in the spacer layer **118** may be equal to about $2 \times 10^{18} \text{ cm}^{-3}$.

With continued reference to FIG. 1A, the semiconductor structure **100** may further include an optional $\text{In}_{cp}\text{Ga}_{1-cp}\text{N}$ cap layer **120** disposed between the active region **106** and the p-type contact layer **104**. The optional $\text{In}_{cp}\text{Ga}_{1-cp}\text{N}$ cap layer **120** may comprise a layer of $\text{In}_{cp}\text{Ga}_{1-cp}\text{N}$, wherein $0.01 \leq cp \leq 0.10$, or wherein $0.03 \leq cp \leq 0.07$. As one particular

non-limiting example, the value of c_p may be equal to about 0.05. The $\text{In}_{c_p}\text{Ga}_{1-c_p}\text{N}$ cap layer **120** may be used to avoid the dissolution and/or evaporation of indium in the underlying layers of the active region **106** upon subsequent processing at elevated temperatures, and/or may serve the same function of a spacer layer.

The $\text{In}_{c_p}\text{Ga}_{1-c_p}\text{N}$ cap layer **120** may have an average layer thickness T_{cp} of between about one nanometer (1 nm) and about one hundred nanometers (100 nm), or between about one nanometer (1 nm) and about twenty five nanometers (25 nm). As one particular non-limiting example, T_{cp} may be equal to about ten nanometers (10 nm). Optionally, the cap layer **120** may be doped. For example, the cap layer **120** may be doped p-type by doping with elements that are electron acceptors, such as magnesium, zinc, and carbon. In other embodiments, however, the cap layer **120** may be doped n-type. The concentration of dopants in the cap layer **120** may range from about $3 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{19} \text{ cm}^{-3}$, or may range from about $1 \times 10^{18} \text{ cm}^{-3}$ to about $5 \times 10^{18} \text{ cm}^{-3}$. As one particular non-limiting example, the concentration of dopants in the cap layer **120** may be about $2 \times 10^{18} \text{ cm}^{-3}$ in some embodiments.

The semiconductor structure **100** of the present disclosure may further include one or more electron blocking layers (EBLs) disposed between the active region **106** and the p-type contact layer **104**. Such electron blocking layers may comprise a material in which the energy level of the band edge of the conduction band is relatively high compared to the band edge in the conduction band in the active region **106**, which may serve to confine electrons within the active region **106** and prevent carriers from over flowing out from the active region **106**.

As a non-limiting example, FIG. 1A illustrates an electron blocking layer **108** disposed on a side of the cap layer **120** opposite the active region **106**. In embodiments including a p-type bulk layer **110**, as shown in FIG. 1A, the electron blocking layer **108** may be disposed directly between the cap layer **120** and the p-type bulk layer **110**.

The electron blocking layer **108** comprises a Group III nitride. As a non-limiting example, the electron blocking layer **108** may be at least substantially comprised by $\text{In}_c\text{Ga}_{1-c}\text{N}$ (but for the presence of dopants), wherein $0.00 \leq c \leq 0.02$ and may, in some embodiments, be at least substantially comprised by GaN (but for the presence of dopants). In further embodiments, the electron blocking layer **108** may be at least substantially comprised by $\text{Al}_c\text{Ga}_{1-c}\text{N}$, wherein $0.00 \leq c \leq 0.20$. In some embodiments, the electron blocking layer **108** may be at least substantially comprised by $\text{Al}_c\text{Ga}_{1-c}\text{N}$ (but for the presence of dopants).

The electron blocking layer **108** may be doped p-type with one or more dopants selected from the group consisting of magnesium, zinc, and carbon. A concentration of the one or more dopants within the electron blocking layer **108** may be in a range extending from about $1 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{21} \text{ cm}^{-3}$, or in some embodiment may be equal to about $3 \times 10^{19} \text{ cm}^{-3}$. In some embodiments, the electron blocking layer **108** may have an average layer thickness T_e in a range extending from about five nanometer (5 nm) to about fifty nanometers (50 nm), or may, in some embodiments, have an average layer thickness T_e equal to about twenty nanometers (20 nm).

In further embodiments of the semiconductor structure **100** of the present disclosure, the semiconductor structure **100** may have an electron blocking layer, similar to the electron blocking layer **108**, but wherein the electron blocking layer has a superlattice structure comprising alternating layers of different materials, as illustrated in the inset **122** of FIG. 1A. For example, the electron blocking layer **108** may have a superlattice structure comprising alternating layers of GaN

124 and $\text{In}_e\text{Ga}_{1-e}\text{N}$ **124** wherein $0.01 \leq e \leq 0.02$. In further embodiments, the electron blocking layer may have a superlattice structure comprising alternating layers of GaN **124** and $\text{Al}_e\text{Ga}_{1-e}\text{N}$ **126**, wherein $0.01 \leq e \leq 0.20$. Each of the layers in such superlattice structures may have an average layer thickness of from about one nanometer (1 nm) to about twenty nanometers (20 nm).

As previously mentioned, the semiconductor structure **100** of the present disclosure may further include a p-type bulk layer **110** disposed between the electron blocking layer **108** and the p-type contact layer **104**. Such p-type bulk layers may comprise a p-doped Group III nitride material, such as p-doped $\text{In}_p\text{Ga}_{1-p}\text{N}$. Such p-type bulk layers may be used, for example, as a source of hole carriers and to enhance the electrical conduction and light extraction to and from the active region **106**.

The p-type bulk layer **110** may be at least substantially comprised by $\text{In}_p\text{Ga}_{1-p}\text{N}$, wherein $0.01 \leq p \leq 0.08$ (but for the presence of dopants). As one particular non-limiting example, the p-type bulk layer **110** may be at least substantially comprised by $\text{In}_p\text{Ga}_{1-p}\text{N}$, wherein p is equal to about 0.02. The p-type bulk layer **110** may be doped p-type with one or more dopants selected from the group consisting of magnesium, zinc, and carbon. A concentration of the one or more dopants within the p-type bulk layer **110** may be in a range extending from about $1 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{21} \text{ cm}^{-3}$. As one particular non-limiting example, the concentration of dopants in the p-type bulk layer **110** may be equal to about $3 \times 10^{19} \text{ cm}^{-3}$. In some embodiments, the p-type bulk layer **110** may have an average layer thickness T_p in a range extending from about fifty nanometers (50 nm) to about six hundred nanometers (600 nm). As one particular non-limiting example, the p-type bulk layer **110** may have an average layer thickness T_p equal to about one hundred seventy-five nanometers (175 nm).

The semiconductor structure **100** may further include a p-type contact layer **104** disposed on a side of the p-type bulk layer **110** opposite the electron blocking layer **108**. The p-type contact layer **104** may comprise a Group III nitride. Such p-type contact layers may be used, for example, to enhance the conduction of holes into the active region **106**. The p-type contact layer **104** may comprise a higher concentration of one or more dopants, such as p-type dopants, so as to limit the electrical resistance of an electrode contact formed over a portion of p-type contact layer during the fabrication of a light emitting device from semiconductor structure **100**.

As a non-limiting example, the p-type contact layer **104** may comprise $\text{In}_c\text{Ga}_{1-c}\text{N}$ that is doped p-type. For example, the p-type contact layer **104** may be at least substantially comprised by $\text{In}_c\text{Ga}_{1-c}\text{N}$, wherein $0.01 \leq c \leq 0.10$ (but for the presence of dopants), and, in some embodiments, the p-type contact layer **104** may be at least substantially comprised by GaN (but for the presence of dopants). The p-type contact layer **104** may be doped p-type with one or more dopants selected from the group consisting of magnesium, zinc, and carbon. A concentration of the one or more dopants within the p-type contact layer **104** may be in a range extending from about $1 \times 10^{17} \text{ cm}^{-3}$ to about $1 \times 10^{21} \text{ cm}^{-3}$. As one particular non-limiting example, the concentration of the one or more dopants within the p-type contact layer **104** may be equal to about $1 \times 10^{20} \text{ cm}^{-3}$. The p-type contact layer **104** may have an average layer thickness T_c in a range extending from about two nanometers (2 nm) to about fifty nanometers (50 nm). As one particular non-limiting example, the p-type contact layer **104** may have an average layer thickness T_c equal to about

13

fifteen nanometers (15 nm). As shown in FIG. 1A, the p-type contact layer 104 may be formed directly on the p-type bulk layer 110.

As described in greater detail hereinbelow, the completed semiconductor structure 100 may be utilized in the fabrication of one or more semiconductor light emitting devices, such as an LED. In brief, an electrode contact may be formed over a portion of the semiconductor layers of the base layer 102, such as over a portion of the GaN base layer 112, and a further electrode contact may be formed over a portion of the p-type contact layer 104, thereby allowing charge carriers to be injected into the active region 106 with a resultant emission of electromagnetic radiation, which may be in the form of visible light.

FIG. 1B is a simplified diagram illustrating the relative differences in the energy level of the conduction band 128 (in an energy band diagram) for the different semiconductor materials in the various layers of the semiconductor structure 100 of FIG. 1A (note the support substrate 658 and the bonding layer 660 are omitted). FIG. 1B is vertically aligned with the semiconductor structure 100 of FIG. 1A. The vertical dashed lines in FIG. 1B are aligned with the interfaces between the various layers in the semiconductor structure 100 of FIG. 1A. The vertical axis in FIG. 1B is energy, with higher energy levels being located vertically above lower energy levels. It should be noted that FIG. 1B illustrates a non-limiting example of the conduction band energy levels for an example semiconductor structure 100. As a result, the relative horizontal conduction band energy levels may alter in relative position as a function of at least the composition and doping of the individual semiconductor layers, the composition ranges of the various semiconductors layers ranging as described hereinabove. Thus, FIG. 1B may be used to see the relative differences in the energy levels of the conduction band 128 in the various layers of the semiconductor structure 100. As shown in FIG. 1B, the energy level of the conduction band 128 in the well layer 114 may be lower than the energy level of the conduction band 128 in other layers of the semiconductor structure 100.

As known in the art, for Group III nitride layers, such as InGa_N, the energy level of the conduction band 128 is a function of multiple variables, including, but not limited to, indium content and dopant levels. The well layers 114 and the barrier layers 116 may be formed to have a composition and otherwise configured such that the energy level of the conduction band 128 in the well layers 114 is lower than the energy level of the conduction band 128 in the barrier layers 116. As a result, charge carriers (e.g., electrons) may be accumulated in the well layers 114 during operation of a light emitting device fabricated from the semiconductor structure 100, and the barrier layers 116 may serve to impede migration of charge carriers (e.g., electrons) across the active region 106. Thus, in some embodiments, the indium content in each well layer 114 may be higher than the indium content in each barrier layer 116. For example, a difference between the indium content in each well layer 114 and the indium content in each barrier layer 116 may be greater than or equal to about 0.05 (i.e., $w-b \geq 0.05$), or in some embodiments may be greater than or equal to about 0.20 (i.e., $w-b \geq 0.20$). In some embodiments, the dopant concentration in the barrier layers 116 may be different than the dopant concentration in the well layers 114. High doping concentrations may result in defects in the crystal structure of InGa_N, and such defects may result in non-radiative combinations of electron-hole pairs. In some embodiments, the dopant concentration in the well layers 114 may be lower than the dopant concentration in the barrier layers 116 to reduce a rate of non-radiative combinations of

14

electron-hole pairs in the well layers 114 relative to the rate of non-radiative combinations of electron-hole pairs in the barrier layers 116. In other embodiments, the dopant concentration in the barrier layers 116 may be higher than the dopant concentration in the well layers 114.

As illustrated in FIG. 1B, the energy barrier provided by the electron blocking layer 108 may result from the difference in the energy level of the conduction band 128 in the electron blocking layer 108 and the cap layer 120 (or other layer immediately adjacent the electron blocking layer 108 on the side thereof closest to the active region 106). The height of the energy barrier may be altered by altering the composition of the electron blocking layer 108. For example, as illustrated in FIG. 1B, the conduction energy level 130 (shown as a solid line) may illustrate the conduction band energy level for an electron blocking layer at least substantially comprised by GaN (but for the presence of dopants). The conduction band energy level within the electron blocking layer may be reduced relative to a GaN electron blocking layer, as illustrated by conduction band energy level 132 (shown as dashed line) by forming an electron blocking layer at least substantially comprised by In_eGa_{1-e}N, wherein $0.01 \leq e \leq 0.02$. In further embodiments, the conduction band energy level may be increased, relative to a GaN electron blocking layer, as illustrated by conduction band energy level 134 (shown as dashed line) by forming an electron blocking layer at least substantially comprised by Al_eGa_{1-e}N, wherein $0.01 \leq e \leq 0.20$. Therefore the energy level of the conduction band within the electron blocking layer may be altered to provide a desired conduction band off-set between the electron blocking layer 108 and the other group III nitride layers of the semiconductor structure 100.

In embodiments of the semiconductor structure 100 in which the electron blocking layer 108 has a superlattice structure comprising alternating layers of different materials, the conduction band energy level may increase and decrease in a periodic like manner as illustrated in the inset 136 of FIG. 1B. For example, the electron blocking layer 108 may have a superlattice structure comprising alternating layers of GaN 138 and Al_eGa_{1-e}N 140, wherein $0.01 \leq e \leq 0.20$, or alternatively, the superlattice structure may comprise alternating layers of GaN and In_eGa_{1-e}N, wherein $0.01 \leq e \leq 0.02$. The magnitude of the conduction band energy off-set between the alternating layers of different materials may be selected by the compositional difference between the GaN layers and the Al_eGa_{1-e}N or In_eGa_{1-e}N layers.

Semiconductor structures of the present disclosure may further include electron stopping layers disposed between the active region of the semiconductor structure and the GaN base layer of the semiconductor structure. Such electron stopping layers may comprise an n-doped Group III nitride material in which the energy level of the band edge of the conduction band is relatively higher compared to the band edge in the conduction band in the GaN base layer and/or the In_{sp}Ga_{1-sp}N base layer, which may serve to further confine electrons within the active region and may prevent overflow of carriers from the active region, thereby providing an improved uniformity of carriers within the active region.

As a non-limiting example, FIGS. 2A and 2B illustrate an embodiment of a semiconductor structure 200 that includes such an electron stopping layer 202. The semiconductor structure 200 is similar to semiconductor structure 100 and includes an active region 106 comprising one or more InGa_N well layers 114 and one or more InGa_N barrier layers 116 as previously described in relation to the semiconductor structure 100. The semiconductor structure 200 also includes a base layer 102, a spacer layer 118, a cap layer 120, an electron

15

blocking layer **108**, a p-type bulk layer **110** and a p-type contact layer **104** as previously described in relation to the semiconductor structure **100**. The electron stopping layer **202** of the semiconductor structure **200** is disposed between the GaN base layer **112** and the spacer layer **118**.

The electron stopping layer **202** comprises a Group III nitride. As a non-limiting example, the electron stopping layer **202** may comprise AlGa_N that is doped n-type. For example, in some embodiments, the electron stopping layer **202** may be at least substantially comprised by Al_{st}Ga_{1-st}N (but for the presence of dopants), wherein $0.01 \leq st \leq 0.20$. In other embodiments, the electron stopping layer **202** may have a superlattice structure, as illustrated in inset **204**, comprising alternating layers of Al_{st}Ga_{1-st}N **206**, wherein $0.01 \leq st \leq 0.20$, and layers of GaN **208**. The semiconductor structure **200** may include any number (e.g., from about one (1) to about twenty (20)) of alternating layers of Al_{st}Ga_{1-st}N **206** and layers of GaN **208**. The layers **206** and **208** in such a superlattice structure may have an average layer thickness of from about one nanometer (1 nm) to about one hundred nanometers (100 nm).

The electron stopping layer **202** may be doped n-type with one or more dopants selected from the group consisting of silicon and germanium. A concentration of the one or more dopants within the electron stopping layer **202** may be in a range extending from about $0.1e^{18} \text{ cm}^{-3}$ to $20e^{18} \text{ cm}^{-3}$. In some embodiments, the electron stopping layer **202** may have an average layer thickness T_{st} in a range extending from about one nanometer (1 nm) to about fifty nanometers (50 nm).

FIG. 2B is a simplified conduction band diagram and illustrates the relative energy levels of the conduction band **228** for the various materials in the semiconductor structure **200**. As shown in FIG. 2B, in the embodiment of the semiconductor structure **200** of FIG. 2A, the energy level of the conduction band **228** within at least a portion of the electron stopping layer **202** of the semiconductor structure **200** (FIG. 2B) is relatively higher than the energy level of the conduction band **200** within the GaN base layer **112** and/or the energy level of the conduction band **228** within the spacer layer **118**. In embodiments wherein the electron stopping layer **202** comprises a superlattice structure, as illustrated in the inset **210** of FIG. 2B, comprising alternating layers of Al_{st}Ga_{1-st}N **206** wherein $0.01 \leq st \leq 0.20$ and layers of GaN **208**, the conduction band energy level may vary in periodic manner.

In additional embodiments, semiconductor structures of the present disclosure may include one or more layers of material between the active region and the GaN base layer that are employed to facilitate fabrication of the semiconductor structure. For example, in some embodiments, the semiconductor structure, and the one or more light emitting devices fabricated from such structures, of the present disclosure may include one or more strain relief layers disposed between the active region and the GaN base layer, wherein the strain relief layers are composed and configured to accommodate strain in the crystal lattice of the crystal structures of the various layers of the semiconductor structure between the GaN base layer and the p-type contact layer, which layers may be grown epitaxially one upon one another in a layer-by-layer process.

As a non-limiting example, FIGS. 3A and 3B illustrate an embodiment of a semiconductor structure **300** that includes such a strain relief layer **302**. The semiconductor structure **300** is similar to semiconductor structure **100** and includes an active region **106** comprising one or more InGa_N well layers **114** and one or more InGa_N barrier layers **116** as previously described in relation to the semiconductor structure **100**. The semiconductor structure **300** also includes a base layer **102**, a

16

spacer layer **118**, a cap layer **120**, an electron blocking layer **108**, a p-type bulk layer **110** and a p-type contact layer **104** as previously described in relation to the semiconductor structure **100**. The strain relief layer **302** of the semiconductor structure **300** is disposed between the GaN base layer **112** and the spacer layer **118**. In the embodiment of FIGS. 3A and 3B, the strain relief layer **302** is disposed directly between the GaN base layer **112** and the In_{spa}Ga_{1-spa}N spacer layer **118**.

The strain relief layer **302** may comprise a Group III nitride. As a non-limiting example, the strain relief layer **302** may have a superlattice structure, as illustrated in inset **304**, comprising alternating layers of In_{sra}Ga_{1-sra}N **306**, wherein $0.01 \leq sra \leq 0.10$, and layers of In_{srb}Ga_{1-srb}N **308**, wherein $0.01 \leq srb \leq 0.10$. Further, sra may be greater than srb. The semiconductor structure **300** may include any number (e.g., from about one (1) to about twenty (20)) of alternating layers of In_{sra}Ga_{1-sra}N layers **306** and In_{srb}Ga_{1-srb}N **308**. The layers **306** and **308** in such a superlattice structure may have an average layer thickness of from about one nanometer (1 nm) to about twenty nanometers (20 nm).

The strain relief layer **302** may be doped n-type with one or more dopants selected from the group consisting of silicon and germanium. A concentration of the one or more dopants within the strain relief layer **302** may be in a range extending from about $0.1e^{18} \text{ cm}^{-3}$ to $20e^{18} \text{ cm}^{-3}$. In some embodiments, the strain relief layer **302** may have an average layer thickness in a range extending from about one nanometer (1 nm) to about fifty nanometers (50 nm).

FIG. 3B is a simplified conduction band diagram and illustrates the relative energy levels of the conduction band **328** for the various materials in the semiconductor structure **300**. As shown in FIG. 3B, in the embodiment of the semiconductor structure **300** of FIG. 3A, the energy level of the conduction band **328** within at least a portion of the strain relief layer **302** of the semiconductor structure **300** (FIG. 3A) may be relatively lower than the energy level of the conduction band **328** within the GaN base layer **112** and/or the energy level of the conduction band **328** within the spacer layer **118**. In other embodiments, the energy level of the conduction band **328** within at least a portion of the strain relief layer **302** of the semiconductor structure **300** (FIG. 3A) may be relatively higher than the energy level of the conduction band **328** within the InGa_N base layer **112** and/or the energy level of the conduction band **328** within the spacer layer **118**. In embodiments in which the strain relief layer **302** comprises a superlattice structure, as illustrated in inset **310** of FIG. 3B, comprising alternating layers In_{sra}Ga_{1-sra}N layers **306** and In_{srb}Ga_{1-srb}N **308**, the conduction band energy level may vary in periodic manner.

FIGS. 4A and 4B illustrate yet another embodiment of a semiconductor structure **400** of the present disclosure. The semiconductor structure **400** is similar to the semiconductor structure **100** and includes an active region **406** comprising one or more InGa_N well layers **114** and one or more InGa_N barrier layers **116** as previously described in relation to the semiconductor structure **100**. The semiconductor structure **400** also includes a base layer **102**, a spacer layer **118**, a cap layer **120**, an electron blocking layer **108**, a p-type bulk layer **110** and a p-type contact layer **104** as previously described in relation to the semiconductor structure **100**. The active region **406** of the semiconductor structure **400** further includes additional GaN barrier layers **402**. Each of the additional GaN barrier layers **402** may be disposed between an InGa_N well layer **114** and an InGa_N barrier layer **116**. The additional GaN barrier layers **402** may serve to further confine electrons

within the well layers 114, where they may be more likely to recombine with holes and result in an increased probability of emission of radiation.

In some embodiments, each GaN barrier layer 402 may be doped n-type with one or more dopants selected from the group consisting of silicon and germanium. For example, a concentration of the one or more dopants within the GaN barrier layers 402 may be in a range extending from about $1.0 \times 10^{17} \text{ cm}^{-3}$ to $5.0 \times 10^{17} \text{ cm}^{-3}$. In some embodiments, each GaN barrier layer 402 may have an average layer thickness T_{b2} in a range extending from about one-half of a nanometer (0.5 nm) to about twenty nanometers (20 nm).

FIG. 4B is a simplified conduction band diagram and illustrates the relative energy levels of the conduction band 428 for the various materials in the semiconductor structure 400. As shown in FIG. 4B, in the embodiment of the semiconductor structure 400 of FIG. 4A, the energy level of the conduction band 428 within the GaN barrier layers 402 (FIG. 4A) may be relatively higher than the energy level of the conduction band 428 within the InGaN barrier layers 116 and higher than the energy level of the conduction band 428 within the InGaN well layers 114.

FIGS. 5A and 5B illustrate yet further embodiments of the present disclosure comprising a semiconductor structure 500. In these embodiments, methods as disclosed in U.S. patent application Ser. No. 13/362,866, which was filed Jan. 31, 2012 in the name of Arena et al., may be utilized for forming an active region 506. The semiconductor structure 500 is similar to the semiconductor structure 100 and includes an active region 506 comprising one or more InGaN well layers 514 and one or more InGaN barrier layers 516 as previously described in relation to the semiconductor structure 100. The semiconductor structure 500 also includes a base layer 102, a spacer layer, a cap layer, an electron blocking layer 108, a p-type bulk layer 110 and a p-type contact layer 104 as previously described in relation to the semiconductor structure 100. For clarity, only the layers surrounding the active region 506 are illustrated, and these layers may comprise the optional spacer layer 118 and cap layer 120 as well as the GaN base layer 112 and the electron blocking layer 108. If the optional layers are omitted from the semiconductor structure 500, the active region 506 may be disposed directly between the GaN base layer 112 and the electron blocking layer 108.

The active region 506 of the semiconductor structure 500 is similar to the active region of semiconductor structure 100, but further includes two or more InGaN barrier layers wherein the band-gap energy between subsequent barrier layers increases in a step-wise manner from right to left as viewed in FIG. 5A and FIG. 5B, i.e., in the direction extending from the cap layer 120 to the spacer layer 118. Such a configuration of the active region 506 in the semiconductor structure 500 may assist in confinement of charge carriers within the active region 506 by preventing overflow of carriers out from the active region 506, thereby increasing the efficiency of light emitting devices fabricated from the semiconductor structure 500.

The barrier regions 516_A-516_C may have a material composition and structural configuration selected to provide each of the barrier regions 516_A-516_C with respective band-gap energies 550_A-550_C, where the band-gap energy is given by the energy difference between the conduction band energy 528 and the valence band energy 552 of each of the semiconductor materials comprising the semiconductor structure 500. The band-gap energy 550_A in the first barrier region 516_A may be less than the band-gap energy 550_B in the second barrier region 516_B, and the band-gap energy 550_B in the second barrier region 516_B may be less than the band-gap energy

550_C in the third barrier region 516_C, as shown in the energy band diagram of FIG. 5B. Further, each of the band-gap energies 552_A-552_C of the quantum well regions 514_A-514_C may be substantially equal and may be less than each of the band-gap energies 550_A-550_C of the barrier regions 516_A-516_C.

In this configuration, a hole energy barrier 554_A between the first quantum well 514_A and the second quantum well 514_B may be less than a hole energy barrier 554_B between the second quantum well 514_B and the third quantum well 514_C. In other words, the hole energy barriers 554_A-554_C across the barrier regions 516_A-516_C may increase in a step-wise manner across the active region 506 in the direction extending from the cap layer 120 to the spacer layer 118. The electron hole energy barriers 554_A-554_C are the differences in the energies of the valence band 552 across the interfaces between the quantum well regions 514_A-514_C and the adjacent barrier regions 516_A-516_C. As a result of the increasing electron hole energy barriers 554_A-554_C across the barrier regions 516_A-516_C moving from the cap layer 120 toward the spacer layer 108, an increase in the uniformity of distribution of holes may be achieved within the active region 506, which may result in improved efficiency during operation of a light emitting device fabrication from semiconductor 500.

As previously mentioned, the barrier regions 516_A-516_C may have a material composition and structural configuration selected to provide each of the barrier regions 516_A-516_C with their different, respective band-gap energies 550_A-550_C. By way of example and not limitation, each barrier region 516_A-516_C may comprise a ternary III-nitride material, such as $\text{In}_{b3}\text{Ga}_{1-b3}\text{N}$, wherein b3 is at least about 0.01. Decreasing the indium content (i.e., decreasing the value of b3) in the $\text{In}_{b3}\text{Ga}_{1-b3}\text{N}$ of the barrier regions 516_C may increase the band-gap energy of the barrier regions 516_A-516_C. Thus, the second barrier region 516_B may have a lower indium content relative to the first barrier region 516_A, and the third barrier region 516_C may have a lower indium content relative to the second barrier region 516_B. In addition, the barrier regions 516_A-516_C and well regions 514_A-514_C may be doped and may have average layer thickness as previously described with respect to semiconductor structure 100.

As previously mentioned, in accordance with embodiments of the present disclosure, the active region 106 (of FIG. 1A) may comprise at least one InGaN well layer and at least one InGaN barrier layer, and, in some embodiments, may be at least substantially comprised of InGaN (e.g., may consist essentially of InGaN, but for the presence of dopants). A majority of previously known light emitting device structures that comprise InGaN well layers include GaN (at least substantially free of indium) barrier layers. The difference in the energy level of the conduction band between InGaN well layers and GaN barrier layers is relatively high, which, according to teachings in the art, provides improved confinement of charge carriers within the well layers and may result in improved efficiency of the LED structures. However, the prior art structures and methods may result in a decrease in device efficiency due to carrier overflow and piezoelectric polarization.

In carrier overflow theory, the one or more quantum well layers may be analogous to a water bucket, with their capability to capture and hold injected carriers diminishing at higher injection of carriers. When injected carriers are not captured or held, they overflow the active region and are wasted, contributing to a drop in device efficiency. In prior art structures comprising InGaN quantum wells and GaN barrier layers, the band off-set, i.e., the difference in conduction band energy levels between the quantum wells and barriers is sig-

nificantly greater than the band off-set for an active region substantially comprised of InGa_N, as described in the embodiments herein. The reduction in the band off-set in the structures described herein allows the injected carriers to more efficiently distribute across the quantum well regions of the active region, thereby increasing the efficiency of light emitting devices fabricated from the semiconductor structures described herein.

In addition, due to lattice mismatch between the InGa_N well layers and the Ga_N barrier layers, a relatively strong piezoelectric polarization occurs within the active region in such light emitting device structures. The piezoelectric polarization may decrease the overlap between the wave functions for the electrons and the wave functions for the holes within the active regions of the light emitting device structures. As disclosed in, for example, J. H. Son and J. L. Lee, "Numerical Analysis of Efficiency Droop Induced by Piezoelectric Polarization in InGa_N/Ga_N Light-Emitting Diodes," *Appl. Phys. Lett.* 97, 032109 (2010), the piezoelectric polarization may result in what is referred to as "efficiency droop" in such light emitting device structures (e.g., LEDs). The efficiency droop phenomena is a droop (a decrease) in a graph of the internal quantum efficiency (IQE) of the LED structure with increasing current density.

Embodiments of light emitting structure, such as LED structures of the present disclosure may alleviate or overcome problems of previously known LED structures that have InGa_N well layers and Ga_N barrier layers associated with lattice mismatch, the carrier overflow, the piezoelectric polarization phenomena, and efficiency droop. Embodiments of LEDs of the present disclosure, such as the LED structure fabricated from semiconductor structure 100 of FIGS. 1A and 1B, may be configured, and the energy band structure thereof designed, such that the active region 106 exhibits a reduced piezoelectric polarization effect, and increased overlap of the wave function of the electrons and the wave function of the holes. As a result, the light emitting device, such as LEDs may exhibit improved uniformity of charge carriers across the active region 106, and reduced efficiency droop with increasing current density.

These advantages that may be attained through embodiments of the present disclosure are further discussed below with reference to FIGS. 10A and 10B, 11A-11E, 12A and 12B, and 13A-13E. FIGS. 10A and 10B illustrate an embodiment of an LED 556 similar to previously known LEDs. The LED 556 includes an active region 558 comprising five (5) InGa_N well layers 562 with Ga_N barrier layers 564 disposed between the InGa_N well layers 562. The LED 556 also includes a base layer 560, a first spacer layer 566, a second spacer layer 568, an electron blocking layer 570, and an electrode layer 572. In the LED 556, the InGa_N well layers 562 comprise layers of In_{0.18}Ga_{0.82}N, each having an average layer thickness of about two and one-half nanometers (2.5 nm). The barrier layers 564 comprise layers of Ga_N, which may have an average layer thickness of about ten nanometers (10 nm). The base layer 560 comprises a layer of doped Ga_N having an average layer thickness of about three hundred twenty-five nanometers (325 nm), which is doped n-type with silicon at a concentration of about 5e¹⁸ cm⁻³. The first spacer layer 566 may comprise undoped Ga_N having an average layer thickness of about twenty-five nanometers (25 nm). The second spacer layer 568 also may comprise undoped Ga_N having an average layer thickness of about twenty-five nanometers (25 nm). The electron blocking layer may comprise p-doped AlGa_N. The electrode layer 572 may comprise a layer of doped Ga_N, such electrode layer may have an average layer thickness of about one hundred twenty-five

nanometers (125 nm), which is doped p-type with magnesium at a concentration of about 5e¹⁷ cm⁻³. FIG. 10B is a simplified conduction band diagram similar to that of FIG. 1B, and illustrates the relative differences in the energy level of the conduction band 574 (in an energy band diagram) for the different materials in the various layers of the LED 556 of FIG. 10A. The vertical dashed lines in FIG. 10B are aligned with the interfaces between the various layers in the LED 556 of FIG. 10A.

As known in the art, the 8x8 Kane Model disclosed in, for example, S. L. Chuang and C. S. Chang, "k·p Method for Strained Wurtzite Semiconductors," *Phys. Rev. B* 54, 2491 (1996), may be used to characterize the structure of the valence band for group-III nitride materials such as Ga_N and InGa_N. The splitting of the heavy, light, and split-off branches of the valence bands in the center of the Brillouin zone may be assumed to be independent of the built-in electric field. Therefore, the valence subbands may be obtained from the solution of coupled Poisson and transport equations. The wave functions of electrons and holes may be assumed to be in the form:

$$u_n \Psi_v \cdot \exp(k_n \cdot r), \text{ and}$$

$$u_{p,s} \Psi_{v,s} \exp(k_p \cdot r),$$

respectively, wherein u_n and $u_{p,s}$ are the Bloch amplitudes of electrons and holes corresponding to the center of the Brillouine zone, k_n and k_p are in-plane quasi-moment vectors, Ψ_v and $\Psi_{v,s}$ are the envelope functions, and the subscript "s" can be heavy (hh), light (lh), or split-off (so) holes. The one-dimensional Schrodinger equations for electron and hole envelope functions are:

$$-\frac{\hbar^2}{2m_n''} \frac{d^2 \Psi_v}{dz^2} + U_{C,v}^{\text{eff}} \Psi_v = E_v \Psi_v, \text{ and}$$

$$-\frac{\hbar^2}{2m_p''} \frac{d^2 \Psi_{v,s}}{dz^2} + U_{V,s}^{\text{eff}} \Psi_{v,s} = E_{v,s} \Psi_{v,s},$$

respectively, wherein U_{hd}^{eff} and U_{vs}^{eff} are the effective potential for electrons and holes in the quantum well, E_v and $E_{v,s}$ are electron and hole energy levels, and m_n'' and m_p'' are electron and hole effective mass in the epitaxial growth direction. By solving the above Schrodinger equations with corresponding boundary conditions, the overlap integral between the electron and hole wave functions is then obtained from:

$$\langle \Psi_i^e | \Psi_j^h \rangle = \int_{-\infty}^{\infty} \Psi_i^e(z) \Psi_j^h(z) dz.$$

As disclosed in S. L. Chuang, *Physics of Phonic Devices*, 2nd Ed. (Wiley, N.J., 2009), the rate of radiative recombination of electrons and holes may be given by:

$$R^{\text{rad}} = B \cdot np \cdot \left[1 - \exp\left(-\frac{F_n - F_p}{kT}\right) \right],$$

where B is the radiative recombination coefficient, n is the electron concentration, p is the hole concentration, and $F_n - F_p$ is the quasi-Fermi level separation. Electron and hole concentration and quasi-Fermi level separation varies with position across the active region of an LED. The maximum radia-

tive recombination rate may be identified in any quantum well and considered as the peak radiative recombination rate for that respective quantum well.

FIG. 11A is a graph illustrating the calculated energy of the band edge of the conduction band 574 and the valence band 576 for the LED 556 of FIGS. 10A and 10B, with zero applied current across the LED 556, as a function of position (in nanometers) across the LED 556 beginning at the surface of the base layer 560 opposite the active region 558. FIG. 11B is a graph similar to that of FIG. 11A, but illustrating the calculated energy of the band edge of the conduction band 574 and the valence band 576 for the LED 556 of FIGS. 10A and 10B at an applied current density across the LED 556 of one hundred twenty-five amps per square centimeter (125 A/cm²). FIG. 11C is a graph that illustrates the calculated intensity as a function of wavelength for each of the five quantum well layers 562 of the LED 556 with the applied current density across the LED 556 of one hundred twenty-five amps per square centimeter (125 A/cm²). QW1 is the leftmost quantum well layer 562, and QW5 is the rightmost quantum well layer 562 from the perspective of FIGS. 10A and 10B. FIG. 11D illustrates the calculated injection efficiency of the LED 556 as a function of applied current density. As shown in FIG. 11D, the LED 556 may exhibit an injection efficiency of about 75.6% at an applied current density of 125 A/cm². FIG. 11E illustrates the calculated internal quantum efficiency (IQE) of the LED 556 as a function of applied current density. As shown in FIG. 11E, the LED 556 may exhibit an internal quantum efficiency of about 45.2% at an applied current density of 125 A/cm². As also shown in FIG. 11E, the internal quantum efficiency of the LED 556 may drop from over 50% at an applied current density of about 20 A/cm² to under 40% at an applied current density of 250 A/cm². As previously discussed, such a drop in the IQE is referred to in the art as efficiency droop.

Table 1 below shows the calculated Wave Function Overlap and Peak Radiative Recombination Rate for each of the five quantum well layers 562 in the LED 556 of FIGS. 10A and 10B.

TABLE 1

	QW1	QW2	QW3	QW4	QW5
Wave Function Overlap	0.328	0.326	0.325	0.341	0.362
Peak Radiative Recombination Rate	6.5e ⁻²⁶	3.3e ⁻²⁶	3.3e ⁻²⁶	6.8e ⁻²⁶	2.4e ⁻²⁷

As can be seen from FIG. 11C and Table 1 above, radiative recombinations come principally from the last well layer 562 (closest to the p-doped side, or anode), which is quantum well number five (i.e., QW5) in the LED 556. Further, as shown in FIG. 11E, the LED 556 exhibits efficiency droop, which may result at least in part due to the piezoelectric polarization caused by the use of InGaN well layers 562 and GaN barrier layers 564 as previously discussed herein.

Embodiments of LEDs of the present disclosure that include an active region including at least one InGaN well layer and at least one InGaN barrier layer, such as the active region 106 of the LED 100, may exhibit improved uniformity in the radiative recombinations occurring in the well layers, and may exhibit reduced efficiency droop. A comparison of an embodiment of an LED of the present disclosure with the LED 556 is provided with reference to FIGS. 12A and 12B, and 13A through 13E below.

FIGS. 12A and 12B illustrate another example of an embodiment of an LED 600 of the present disclosure. The

LED 600 includes an active region 106 comprising five (5) InGaN well layers 114 with InGaN barrier layers 116 disposed between the InGaN well layers 114. The InGaN well layers 114 and the InGaN barrier layers 116 may be as previously described in relation to the semiconductor structure 100 with reference to FIGS. 1A and 1B. The LED 600 also includes a base layer 112, a first spacer layer 118, a cap layer 120, and an InGaN electrode layer 104. In the LED 600, the InGaN well layers 114 comprise layers of In_{0.18}Ga_{0.82}N, each having an average layer thickness of about two and one-half nanometers (2.5 nm). The barrier layers 116 comprise layers of In_{0.08}Ga_{0.92}N, and each may have an average layer thickness of about ten nanometers (10 nm). The base layer 112 comprises a layer of doped In_{0.05}Ga_{0.95}N having an average layer thickness of about three hundred nanometers (300 nm), which is doped n-type with silicon at a concentration of about 5e¹⁸ cm⁻³. The first spacer layer 118 may comprise undoped In_{0.08}Ga_{0.92}N having an average layer thickness of about twenty-five nanometers (25 nm). The cap layer 120 also may comprise undoped In_{0.08}Ga_{0.92}N having an average layer thickness of about twenty-five nanometers (25 nm). The electrode layer 104 may comprise a layer of doped In_{0.05}Ga_{0.95}N, that may have an average layer thickness of about one hundred fifty nanometers (150 nm), which is doped p-type with magnesium at a concentration of about 5e¹⁷ cm⁻³. FIG. 12B is a simplified conduction band diagram illustrating the relative differences in the energy level of the conduction band 602 (in an energy band diagram) for the different materials in the various layers of the LED 600 of FIG. 12A.

FIG. 13A is a graph illustrating the calculated energy of the band edge of the conduction band 602 and the valence band 604 for the LED 600 of FIGS. 12A and 12B, with zero applied current across the LED 600, as a function of position (in nanometers) across the LED 600 beginning at the surface of the base layer 112 opposite the active region 106. FIG. 13B is a graph similar to that of FIG. 13A, but illustrating the calculated energy of the band edge of the conduction band 602 and the valence band 604 for the LED 600 of FIGS. 12A and 12B at an applied current density across the LED 600 of one hundred twenty-five amps per square centimeter (125 A/cm²). FIG. 13C is a graph that illustrates the calculated intensity as a function of wavelength for each of the five quantum well layers 108 of the LED 600 with the applied current density across the LED 600 of one hundred twenty-five amps per square centimeter (125 A/cm²). QW1 is the leftmost quantum well layer 108, and QW5 is the rightmost quantum well layer 108 from the perspective of FIGS. 12A and 12B. FIG. 13D illustrates the calculated injection efficiency of the LED 600 as a function of applied current density. As shown in FIG. 13D, the LED 600 may exhibit an injection efficiency of about 87.8% at an applied current density of 125 A/cm², and may exhibit a carrier injection efficiency of at least about 80% over a range of current densities extending from about 20 A/cm² to about 250 A/cm². FIG. 13E illustrates the calculated internal quantum efficiency (IQE) of the LED 600 as a function of applied current density. As shown in FIG. 13E, the LED 600 may exhibit an internal quantum efficiency of about 58.6% at an applied current density of 125 A/cm². As also shown in FIG. 13E, the internal quantum efficiency of the LED 600 may remain between about 55% and about 60% at an applied current density in the range extending from about 20 A/cm² to 250 A/cm². Thus, the LED 600 exhibits very little efficiency droop, and significantly less efficiency droop than the efficiency droop exhibited by the LED 556 (which LED 556 does not conform to embodiments of the present disclosure).

Table 2 below shows the calculated Wave Function Overlap and Peak Radiative Recombination Rate for each of the five quantum well layers **108** in the LED **600** of FIGS. **12A** and **12B**.

TABLE 2

	QW1	QW2	QW3	QW4	QW5
Wave Function Overlap	0.478	0.493	0.494	0.494	0.471
Peak Radiative Recombination Rate	$7.8e^{26}$	$7.7e^{26}$	$7.9e^{26}$	$8.1e^{26}$	$8.3e^{26}$

As can be seen from FIG. **13C** and Table 2 above, radiative recombinations are more uniform across the well layers **108** in the LED **600** compared to the well layers **508** in the LED **500**.

The LED **556** of FIGS. **10A** and **10B** and the LED **600** of FIGS. **12A** and **12B** were modeled using SILENSE® software, which is commercially available from STR Group, Inc. The SILENSE® software was also used to produce the graphs of FIGS. **11A-11E** and **13A-13E**, and to obtain the data set forth in Tables 1 and 2.

In accordance with some embodiments of the present disclosure, the LEDs may exhibit an internal quantum efficiency of at least about 45% over a range of current density extending from about 20 A/cm² to about 250 A/cm², at least about 50% over a range of current density extending from about 20 A/cm² to about 250 A/cm², or even at least about 55% over a range of current density extending from about 20 A/cm² to about 250 A/cm². Further, the LEDs may exhibit an at least substantially constant carrier injection efficiency over a range of current density extending from about 20 A/cm² to about 250 A/cm². In some embodiments, LEDs of the present disclosure may exhibit a carrier injection efficiency of at least about 80% over a range of current densities extending from about 20 A/cm² to about 250 A/cm².

Non-limiting examples of methods that may be utilized to fabricate semiconductor structures and light emitting devices, such as LEDs, of the embodiments of the disclosure are briefly described below with reference to FIGS. **6C** through FIGS. **6D** and examples of light emitting devices fabricated by such methods are described with reference to FIG. **7** and FIG. **8**.

Referring to FIG. **6C**, a growth template **113** (fabricated as previously described hereinabove) may be disposed within a deposition chamber, and layers comprising Group III nitride materials, commonly referred to as the growth stack **682** (see FIG. **6D**), may be epitaxially, sequentially grown on one or more seed layers **656** of the growth template **113**. It should be noted that, although the seed layer is illustrated as one or more islands of Group III nitride material, in some embodiments, the seed layer may comprise a continuous film over the support substrate **658**.

FIG. **6D** illustrates semiconductor structure **680**, comprising a growth template **113** comprising two seed layers **656**, each having various layers of the semiconductor structure **100** of FIGS. **1A** and **1B** deposited thereon. In particular, an GaN base layer **112** of a semiconductor structure **100** is epitaxially deposited directly on each of the seed layer structures **656**, with an InGa_N spacer layer **118**, an InGa_N well layer **114**, an InGa_N barrier layer **116**, an InGa_N cap layer **120**, an electron blocking layer **108**, a p-type bulk layer **110** and a p-type contact layer **104** sequentially, epitaxially deposited over the growth template **113**.

The various layers of the semiconductor structure **680** comprising the growth stack **682**, may be deposited, for

example, using a metalorganic chemical vapor deposition (MOCVD) process and system within a single deposition chamber, i.e., without the need for unloading or unloading the growth stack during the deposition process. The pressure within the deposition chamber may be reduced to between about 50 mTorr and about 500 mTorr. The pressure within the reaction chamber during the deposition process may be increased and/or decreased during the deposition of the growth stack **682** and therefore tailored for the specific layer being deposited. As a non-limiting example, the pressure in the reaction chamber during the deposition of the GaN base layer **112**, the spacer layer **118**, the one or more well layers **114**/barrier layers **116**, the cap layers **120** and the electron barrier layer **108** may range between about 50 mTorr and about 500 mTorr, and may in some embodiments be equal to about 440 mTorr. The pressure within the reaction chamber for the deposition of the p-type bulk layer **110** and the p-type contact layer **104** may range between about 50 mTorr and about 250 mTorr, and may in some embodiments be equal to about 100 mTorr.

The growth template **113** may be heated to a temperature between about 600° C. and about 1,000° C. within the deposition chamber. Metalorganic precursor gases and other precursor gases (and, optionally, carrier and/or purge gases) then may be caused to flow through the deposition chamber and over the one or more seed layers **656** of the growth template **113**. The metalorganic precursor gases may react, decompose, or both react and decompose in a manner that results in the epitaxial deposition of group II nitride layers, such as InGa_N layers, on the growth template **113**.

As non-limiting examples, trimethylindium (TMI) may be used as a metalorganic precursor for the indium of the InGa_N, triethylgallium (TMG) may be used as a metalorganic precursor for the gallium of the InGa_N, triethylaluminum (TMA) may be used as a metalorganic precursor for the AlGa_N, and ammonia may be used as a precursor for the nitrogen of the group III nitride layers. SiH₄ may be used as a precursor for introducing silicon into the InGa_N when it is desired to dope the group III nitride n-type, and Cp₂Mg (bis(cyclopentadienyl) magnesium) may be used as a precursor for introducing magnesium into the group III nitride when it is desired to dope the group III p-type. It may be advantageous to tailor a ratio of the indium precursor (e.g., trimethylindium) to the gallium precursor (e.g., triethylgallium) that will result in indium being incorporated into the InGa_N at a concentration that is near a saturation point for indium in the

InGa_N at the deposition temperature. The percentage of indium incorporated into the InGa_N may be controlled as the InGa_N is epitaxially grown by controlling the growth temperature. Relatively higher amounts of indium will be incorporated at relatively lower temperatures, and relatively lower amounts of indium will be incorporated at relatively higher temperatures. As non-limiting examples, the InGa_N well layers **108** may be deposited at temperatures in a range extending from about 600° C. to about 950° C.

The deposition temperature of the various layers of the growth stack **100** may be increased and/or decreased during the deposition process and therefore tailored for the specific layer being deposited. As a non-limiting example, the deposition temperature during the deposition of the GaN base layer **112**, the p-type bulk layer **110** and the p-type contact layer **104** may range between about 600° C. to about 950° C., and may in some embodiments be equal to about 900° C. The growth rate of the GaN base layer **112** the p-type bulk layer **110** and the p-type contact layer **104** may range between about one nanometer per minute (1 nm/min) to about fifty nanometers per minute (50 nm/min), and in some embodi-

25

ments the growth rate of the GaN base layer **112**, the p-type bulk layer **110** and the p-type contact layer **104** may be equal to about 6 nanometers per minute (6 nm/min).

In additional non-limiting example embodiments, the deposition temperature during the deposition of the spacer layer **118**, the one or more well layers **114**, the one or more barrier layers **116**, the cap layer **120** and the electron blocking layer **108** may range between about 600° C. to about 950° C., and may in some embodiments be equal to about 750° C. The growth rate of the spacer layer **118**, the one or more well layers **114**, the one or more barrier layers **116**, the cap layer **120** and the electron blocking layer **108** may range between about one nanometer per minute (1 nm/min) to about thirty nanometers per minute (30 nm/min), and in some embodiments the growth rate of the spacer layer **118**, the one or more well layers **114**/barrier layers **116**, the cap layer **120** and the electron blocking layer **108** may be equal to about one nanometer per minute (1 nm/min).

In embodiments comprising deposition of InGaN layers, the flow rate ratio of the precursor gases may be selected to provide InGaN layers of high quality. For example, the methods for forming the InGaN layers of semiconductor structure **100** may comprise selecting the gas ratio to provide one or more InGaN layers with a low defect density, substantially free of stain relaxation and substantially free of surface pits.

In non-limiting examples the flow ratio (%) of trimethylindium (TMI) to triethylgallium (TMG) may be defined as:

$$\text{flow ratio (\%)} = \frac{\text{flow rate (TMI)}}{\text{flow rate (TMI + TEG)}} \times 100,$$

and such a flow ratio may be increased and/or decreased during the deposition process and therefore tailored for the specific InGaN layer being deposited. As a non-limiting example, the flow ratio during the deposition of the p-type bulk layer **110** may range from between about 50% to about 95%, and may in some embodiments be equal to about 85%. In further embodiments, the flow ratio during the deposition of the spacer layer **118**, the one or more barrier layers **116** and the cap layer **120** may range between about 1% to about 50%, and may in some embodiments be equal to about 2%. In yet further embodiments, the flow ratio during the deposition of the one or more quantum well layers **114** may range between about 1% to about 50%, and may in some embodiments be equal to about 30%.

The growth template **113** optionally may be rotated within the deposition chamber during the deposition processes. As a non-limiting example, the growth template **113** may be rotated within the deposition chamber during the deposition processes at a rotational speed of between about 50 revolutions per minute (RPM) and about 1500 revolutions per minute (RPM), and may in some embodiments rotate at a rotational speed of equal to about 450 revolutions per minute (RPM). The rotational speed during the deposition process may be increased and/or decreased during the deposition and therefore tailored for the specific layer being deposited. As a non-limiting example the rotational speed of the growth template during the deposition of the GaN base layer **112**, the spacer layer **118**, the one or more well layers **114**, the one or more barrier layers **116**, the cap layers **120** and the electron barrier layer **108** may range between about 50 revolutions per minute (RPM) and about 1500 revolutions per minute (RPM), and may in some embodiments rotate at a rotational speed of equal to about 440 revolutions per minute (RPM). The rotational speed of the growth template **113** during the deposition

26

of the p-type bulk layer **110** and the p-type contact layer **104** may range between about 50 revolutions per minute (RPM) and about 1500 revolutions per minute (RPM), and may in some embodiments rotate at a rotational speed of equal to about 1000 revolutions per minute (RPM).

In embodiments of the semiconductor structures of the present disclosure comprising deposition of Group III nitride, and in particular InGaN layers, the strain energy of the one or more InGaN layers comprising the growth stack **682**, epitaxially deposited over the growth template **113** may affect the efficiency of the light emitting devices fabricated from such semiconductor structures. In some embodiments the total strain energy developed within the growth stack **682** may be related to the efficiency, as defined by the internal quantum efficiency (IQE), of the semiconductor structures of the present disclosure.

In greater detail, the strain energy stored within an n^{th} layer of InGaN is proportional to the average total thickness T_n of the n^{th} layer of InGaN, and to the concentration of indium %In_n in the n^{th} layer of InGaN. In addition, the total strain energy stored with the plurality of InGaN layers comprising the growth stack **682** is proportional to the sum of the average total thickness T_n of each of the InGaN layers and to the concentration of indium %In_n in each of the InGaN layers, therefore the total strain energy within the InGaN layers comprising the growth stack **702** may be estimated using the following relationship:

$$\text{Total strain energy (a.u.)} \propto \sum (\% \text{In}_n \times T_n),$$

wherein the average total thickness T_n of the n^{th} layer is expressed in nanometers (nm) and the concentration of indium in the n^{th} InGaN layer %In_n is expressed as an atomic percentage. For example, if an n^{th} layer of InGaN has an average total thickness T_n of one hundred fifty nanometers (150 nm) and an indium concentration %In_n of 2.0 at %, the strain energy within the n^{th} layer of InGaN may be proportional to about 300 a.u. ($300 = 150(2)$).

FIG. 9 illustrates a graph **900** showing the relationship between IQE (a.u.) and total strain energy (a.u.) for the semiconductor structures of the present disclosure. The IQE of the semiconductor structures of the present disclosure may decrease at a value of total strain energy referred to as the "critical strain energy" of the semiconductor structure, as illustrated by line **902** of graph **900**. The IQE of the semiconductor structures below the critical strain energy (as represented by line **904**) may be substantially greater than the IQE of the semiconductor structures above the critical strain energy (as represented by line **906**). For example, graph **900** illustrates IQE values (as shown by rectangular indicators) for several semiconductor structures of the present disclosure. In some embodiments, the IQE below the critical strain energy may be about 500% greater than the IQE above the critical strain energy. In further embodiments, the IQE below the critical strain energy may be about 250% greater than the IQE above the critical strain energy. In yet further embodiments, the IQE below the critical strain energy may be about 100% greater than the IQE above the critical strain energy.

For the semiconductor structures of the present disclosure, the critical strain energy (a.u.) **902** may have a value of about 1800 (a.u.) or less, about 2800 (a.u.) or less, or even about 4500 (a.u.) or less.

In the present disclosure, the plurality of Group III nitride layers comprising the growth stack **682** of FIG. 6D may be deposited in such a manner that the growth stack **682** is substantially fully strained to match the crystal lattice of the In_xGa_{1-x}N seed layer **656** of growth template **113**. In such embodiments, wherein the growth stack **682** is grown sub-

stantially fully strained, i.e., substantially free of strain relaxation, the growth stack may inherit the lattice parameter of the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer. In certain embodiments of the present disclosure, the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer may exhibit a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms, and the growth stack may exhibit a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms. Therefore, in non-limiting examples, the semiconductor structures **100**, **200**, **300**, **400** and **500** may be formed in such a manner to be composed of fully strained materials, and may have such a growth plane lattice parameter. In some embodiments, the GaN base layer **112** formed over the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** will be grown in a relaxed manner as the GaN base layer **112** is grown lattice matched to the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656**.

In further embodiments, the plurality of Group III nitride layers comprising the growth stack **682** of FIG. **6D** may be deposited in such a manner that the growth stack **682** is partially relaxed, i.e., the lattice parameter of the growth stack **682** differs from the underlying $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer. In such embodiments the percentage strain relaxation (R) may be defined as.

$$R(\%) = \frac{a - a_s}{a_l - a_s} \times 100$$

where a is the average growth plane lattice parameter for the growth stack **682**, a_s is the average growth plane lattice parameter of the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed and a_l is the equilibrium (or natural state) average growth plane lattice parameter for the growth stack. For example, in some embodiments the growth stack **682** may exhibit a percentage strain relaxation (R) of less than about 0.5%, in further embodiments the growth stack **682** may exhibit a percentage strain relaxation (R) of less than about 10% and in yet further embodiments the growth stack **682** may exhibit a percentage strain relaxation (R) of less than about 50%.

After epitaxially depositing the various layers of the semiconductor structures that comprise Group III nitride materials, further processing may be applied to complete the fabrication of the semiconductor structures into light emitting devices, such as LEDs. For example, electrode contacts may be formed on the layers of Group III nitride materials using processes known in the art and briefly described below with reference to FIG. **7** and FIG. **8**.

An example of a light emitting device **700**, such as a LED, fabricated from the semiconductor structure **100** is illustrated in FIG. **7**. Although the following description describes embodiments for fabricating light emitting devices from semiconductor structure **100**, it should be noted that such fabrication processes may also be applied to the semiconductor structures **200**, **300**, **400** and **500**.

In further detail, a portion of the semiconductor structure **100** may be removed thereby exposing a portion of the GaN base layer **112**. The removal of a select portion of the semiconductor structure **100** may be realized by applying a photosensitive chemical to the exposed surface of the p-contact layer **104** of semiconductor structure **100** (not shown). Upon exposure to electromagnetic radiation through a patterned transparent plate and subsequent development, the photosensitive layer may be utilized as a "mask layer" to allow for select removal of the Group III nitride layers above the GaN base layer **112**. Removal of a select portions of the Group III nitride layers above the GaN base layer **112** may comprise an

etching process, for example a wet chemical etch and/or a dry plasma based etch (e.g., reactive ion etching, inductively couple plasma etching).

A first electrode contact **702** may be formed over a portion of the exposed GaN base layer **112**. The first electrode contact **702** may comprise one or more metals which may include titanium, aluminum, nickel, gold and one or more alloys thereof. A second electrode contact **704** may be formed over a portion of the p-contact layer **104**, the second electrode contact **704** may comprise one or more metals layers, which may include nickel, gold, platinum, silver and one or more alloys thereof. Upon formation of the first electrode contact **702** and the second electrode contact **704**, current may be passed through the light emitting device **700** to produce electromagnetic radiation, e.g., in the form of visible light. It should be noted that the light emitting device **700** is commonly referred to as a "lateral device" in the art since at least of portion the current pathway between the first electrode contact **702** and the second electrode contact **704** comprises a lateral pathway.

A further example of a light emitting device **800**, such as a LED, fabricated from the semiconductor structure **100** is illustrated in FIG. **8**, again although the following description describes embodiments for fabricating light emitting devices from semiconductor structure **100**, it should be noted that such fabrication processes may also be applied to the semiconductor structure **200**, **300**, **400** and **500**.

In further detail, all or a portion of the growth template **113** may be removed from semiconductor structure **100** to enable exposure of either the $\text{In}_x\text{Ga}_{1-x}\text{N}$ seed layer **656** or in some embodiment to enable exposure of the GaN base layer **112**. The removal of all or a portion of the growth template **113** may comprise one or more removal methods including wet etching, dry etching, chemical mechanical polishing, grinding and laser lift-off. Upon removal of all or a portion of the growth template **113**, a first electrode contact **802** may be applied to the GaN base layer **112** as described hereinabove. Subsequently a second electrode contact **804** may be applied to a portion of the p-contact layer **104**, thereby forming the light emitting device **800**. Upon formation of the first electrode contact **802** and the second electrode contact **804** current may be passed through the light emitting device **800** to produce electromagnetic radiation, e.g., in the form of visible light. It should be noted that the light emitting device **800** is commonly referred to as a "vertical device" in the art since the current pathway between the first electrode layer **802** and the second electrode layer **804** comprises a substantially vertical pathway.

In addition to the fabrication methods and processes described hereinabove for the fabrication of the non-limiting example light emitting devices **700** and **800**, it should be noted that additional methods and processes known in the art may also be utilized such as, for example, surface roughening to improve light extraction, bonding to metallic carriers to improve thermal dissipation and the process known in the art as "flip-chip bonding" among other well-known fabrication methods.

Light emitting device, such as LEDs according to embodiments of the present disclosure may be fabricated and used in any type of light emitting device that incorporates one or more LEDs therein. Embodiments of LEDs of the present disclosure may be particularly suitable for use in applications that benefit from LEDs that operate under relatively high power and that require relatively high luminosity. For example, LEDs of the present disclosure may be particularly

29

suitable for use in LED lamps and LED-based light bulbs, which may be used for lighting buildings, street lighting, automotive lighting, etc.

Additional embodiments of the present disclosure include luminary devices for emitting light that include one or more LEDs as described herein, such as the light emitting device 700 of FIG. 7 and light emitting device 800 of FIG. 8. As non-limiting examples, the luminary devices may be as described in, for example, U.S. Pat. No. 6,600,175, which issued Jul. 29, 2003 to Baretz et al., the disclosure of which is incorporated herein in its entirety by this reference, but including one or more LEDs as described herein.

FIG. 14 illustrates an example embodiment of a luminary device 900 of the present disclosure that includes a light emitting device, such device 700, 800 as described with reference to FIGS. 7 and 8. As shown in FIG. 14, the luminary device 900 may include a container 902, at least a portion of which is at least substantially transparent to electromagnetic radiation in the visible region of the electromagnetic radiation spectrum. The container 902 may comprise, for example, an amorphous or crystalline ceramic material (e.g., a glass) or a polymeric material. The LED 800 is disposed within the container 902, and may be mounted on a support structure 904 (e.g., a printed circuit board or other substrate) within the container 902. The luminary device 900 further includes a first electrical contact structure 906, and a second electrical contact structure 908. The first electrical contact structure 906 may be in electrical communication with one of the electrode contacts of the LED, such as the first electrode contact 802 (FIG. 8), and the second electrical contact structure 908 may be in electrical communication with the other of the electrode contacts of the LED, such as the second electrode contact 804 (FIG. 8). As a non-limiting example, the first electrical contact structure 906 may be in electrical communication with the first electrode contact 804 through the support structure 904, and a wire 910 may be used to electrically couple the second electrical contact structure 908 with the second electrode contact 804. Thus, a voltage may be applied between the first electrical contact structure 906 and the second electrical contact structure 908 of the luminary device 900 to provide a voltage and corresponding current between the first and second electrode contacts 802, 804 of the LED, thereby causing the LED to emit radiation.

The luminary device 900 optionally may further include a fluorescent or phosphorescent material that will itself emit electromagnetic radiation (e.g., visible light) when stimulated or excited by absorption of electromagnetic radiation emitted by the one or more LEDs 800 within the container 902. For example, an inner surface 912 of the container 902 may be at least partially coated with such a fluorescent or phosphorescent material. The one or more LEDs 800 may emit electromagnetic radiation at one or more specific wavelengths, and the fluorescent or phosphorescent material may include a mixture of different materials that will emit radiation at different visible wavelengths, such that the luminary device 900 emits white light outward from the container 902. Various types of fluorescent and phosphorescent materials are known in the art and may be employed in embodiments of luminary devices of the present disclosure. For example, some such materials are disclosed in the aforementioned U.S. Pat. No. 6,600,175.

Additional non-limiting examples of embodiments of the disclosure are set forth below.

Embodiment 1:

A semiconductor structure, comprising: a GaN base layer having a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms;

30

an active region disposed over the base layer, the active region comprising a plurality of layers of InGa_N, the plurality of layers of InGa_N including at least one In_wGa_{1-w}N well layer, wherein $0.10 \leq w \leq 0.40$, and at least one In_bGa_{1-b}N barrier layer, wherein $0.01 \leq b \leq 0.10$; an electron blocking layer disposed on a side of the active region opposite the GaN base layer; a p-type bulk layer disposed on the electron blocking layer, the p-type bulk layer comprising In_pGa_{1-p}N, wherein $0.01 \leq p \leq 0.08$; and a p-type contact layer disposed on p-type bulk layer, the p-type contact layer comprising In_cGa_{1-c}N, wherein $0.00 \leq c \leq 0.10$.

Embodiment 2:

The semiconductor structure of Embodiment 1, wherein the base layer further comprises a growth template, the growth template comprising: a support substrate; and an In_sGa_{1-s}N seed layer disposed on the support substrate, wherein a growth plane of the In_sGa_{1-s}N seed layer is a polar plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms wherein $0.02 \leq s \leq 0.05$, and wherein the GaN base layer is substantially lattice matched to the growth plane of the In_sGa_{1-s}N seed layer.

Embodiment 3:

The semiconductor structure of Embodiment 2, further comprising an In_{sp}Ga_{1-sp}N spacer layer disposed on the In_sGa_{1-s}N seed layer on a side thereof opposite the GaN base layer, wherein $0.01 \leq sp \leq 0.10$.

Embodiment 4:

The semiconductor structure of any one of Embodiments 1 through 3, further comprising an In_{cp}Ga_{1-cp}N cap layer disposed between the active region and the electron blocking layer, wherein $0.01 \leq cp \leq 0.10$.

Embodiment 5:

The semiconductor structure of any one of Embodiments 1 through 4, wherein the electron blocking layer comprises In_eGa_{1-e}N, wherein $0.01 \leq e \leq 0.02$.

Embodiment 6:

The semiconductor structure of any one of Embodiments 1 through 5, wherein the electron blocking layer is at least substantially comprised of GaN.

Embodiment 7:

The semiconductor structure of any one of Embodiments 1 through 6, wherein the electron blocking layer is at least substantially comprised of Al_eGa_{1-e}N, wherein $0.1 \leq e \leq 0.2$.

Embodiment 8:

The semiconductor structure of Embodiment 7, wherein the electron blocking layer has a superlattice structure comprising alternating layers of GaN and Al_eGa_{1-e}N, wherein $0.1 \leq e \leq 0.2$.

Embodiment 9:

The semiconductor of any one of Embodiments 1 through 9, further comprising an electron stopping layer disposed between the GaN base layer and the active region, wherein the electron stopping layer comprises Al_{st}Ga_{1-st}N, wherein $0.01 \leq st \leq 0.20$.

Embodiment 10:

The semiconductor structure of Embodiment 9, wherein the electron stopping layer has a superlattice structure comprising alternating layers of GaN and Al_{st}Ga_{1-st}N, wherein $0.01 \leq st \leq 0.2$.

Embodiment 11:

The semiconductor structure of any one of Embodiments 1 through 10, further comprising a strain relief layer disposed between the GaN base layer and the active region, the strain relief layer having a superlattice structure comprising alternating layers of In_{sra}Ga_{1-sra}N, wherein $0.01 \leq sra \leq 0.10$, and In_{srb}Ga_{1-srb}N, wherein $0.01 \leq srb \leq 0.10$, and wherein sra is greater than srb.

Embodiment 12:

The semiconductor structure of any one of Embodiments 1 through 11, wherein the active region further comprises an additional barrier layer comprising GaN disposed between the at least one well layer and the at least one barrier layer.

Embodiment 13:

The semiconductor structure of any one of Embodiments 1 through 12, wherein a critical strain energy of the semiconductor structure is about 4500 (a.u.) or less.

Embodiment 14:

The semiconductor structure of any one of Embodiments 1 through 13, wherein the GaN base layer, the active region, the electron blocking layer, the p-type bulk layer and the p-type contact layer define a growth stack exhibiting a percentage strain relaxation of less than 1%.

Embodiment 15:

The semiconductor structure of any one of Embodiments 1 through 14, wherein the p-type contact layer is at least substantially comprised of GaN.

Embodiment 16:

The semiconductor structure of any one of Embodiments 1 through 15, further comprising a first electrode contact over at least a portion of the GaN base layer and a second electrode contact over at least a portion of the p-type contact layer.

Embodiment 17:

A light emitting device, comprising: a GaN base layer having a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms; an active region disposed over the base layer, the active region comprising a plurality of layers of InGa_N, the plurality of layers of InGa_N including at least one well layer, and at least one barrier layer; an electron blocking layer disposed over the active region; a p-type In_pGa_{1-p}N bulk layer disposed over the electron blocking layer; and a p-type In_cGa_{1-c}N contact layer disposed over the p-type In_pGa_{1-p}N bulk layer, wherein a critical strain energy of the light emitting device is about 4500 (a.u.) or less.

Embodiment 18:

The light emitting device of Embodiment 17, wherein the at least one well layer comprises In_wGa_{1-w}N, wherein $0.10 \leq w \leq 0.40$.

Embodiment 19:

The light emitting device of Embodiment 17 or Embodiment 18, wherein the at least one barrier comprises In_bGa_{1-b}N, wherein $0.01 \leq b \leq 0.10$.

Embodiment 20:

The light emitting device of any one of Embodiments 17 through 19, wherein the electron blocking layer is at least substantially comprised of GaN.

Embodiment 21:

The light emitting device of any one of Embodiments 17 through 20, wherein $0.01 \leq p \leq 0.08$ in the p-type In_pGa_{1-p}N bulk layer.

Embodiment 22:

The light emitting device of any one of Embodiments 17 through 21, wherein $0.01 \leq c \leq 0.10$ in the p-type In_cGa_{1-c}N contact layer.

Embodiment 23:

The light emitting device of any one of Embodiments 17 through 22, wherein the p-type In_cGa_{1-c}N contact layer is substantially comprised of GaN.

Embodiment 24:

The light emitting device of any one of Embodiments 17 through 23, further comprising a first electrode contact over at least a portion of the GaN base layer and a second electrode contact over at least a portion of the p-type In_cGa_{1-c}N contact layer.

Embodiment 25:

The light emitting device of any one of Embodiments 17 through 24, wherein the GaN base layer, the active region, the electron blocking layer, the p-type bulk layer and the p-type contact layer define a growth stack exhibiting a percentage strain relaxation of less than 1%.

Embodiment 26:

A method of forming a semiconductor structure, comprising: providing a GaN base layer having a polar growth plane with a growth plane lattice parameter of greater than or equal to about 3.189 Å; growing a plurality of layers of InGa_N to form an active region over the base layer, growing the plurality of layers of InGa_N comprising: growing at least one well layer comprising In_wGa_{1-w}N, wherein $0.10 \leq w \leq 0.40$, and growing at least one barrier layer over the at least one well layer, the at least one barrier layer comprising In_bGa_{1-b}N, wherein $0.01 \leq b \leq 0.10$; growing an electron blocking layer over the active region; growing a p-type In_pGa_{1-p}N bulk layer over the electron blocking layer, wherein $0.01 \leq p \leq 0.08$; and growing a p-type In_cGa_{1-c}N contact layer over the p-type In_pGa_{1-p}N bulk layer, wherein $0.00 \leq c \leq 0.10$.

Embodiment 27:

The method of Embodiment 26, wherein forming the base layer further comprises forming a growth template, forming the growth template comprising: providing a support substrate; and bonding an In_sGa_{1-s}N seed layer to the support substrate, wherein a growth plane of the In_sGa_{1-s}N seed layer is a polar plane with a growth plane lattice parameter of greater than or equal to about 3.189 Angstroms, and wherein $0.02 \leq s \leq 0.05$ in the In_sGa_{1-s}N seed layer.

Embodiment 28:

The method of Embodiment 27, further comprising growing an In_{sp}Ga_{1-sp}N spacer layer over the In_sGa_{1-s}N seed layer on a side thereof opposite the GaN base layer, wherein $0.01 \leq p \leq 0.10$ in the In_{sp}Ga_{1-sp}N spacer layer.

Embodiment 29:

The method of any one of Embodiments 26 through Embodiment 28, further comprising growing an In_{cp}Ga_{1-cp}N cap layer disposed between the active region and the electron blocking layer, wherein $0.01 \leq p \leq 0.10$ in the In_{cp}Ga_{1-cp}N cap layer.

Embodiment 30:

The method of any one of Embodiments 26 through 29, wherein growing the electron blocking layer comprises growing the electron blocking layer to be at least substantially comprised by In_eGa_{1-e}N, wherein $0.00 \leq e \leq 0.02$.

Embodiment 31:

The method of any one of Embodiments 26 through 30, wherein growing the electron blocking layer comprises growing the electron blocking layer to be at least substantially comprised by GaN.

Embodiment 32:

The method of any one of Embodiments 26 through 31, wherein growing the electron blocking layer comprises growing the electron blocking layer to be at least substantially comprised by Al_eGa_{1-e}N, wherein $0.1 \leq e \leq 0.2$.

Embodiment 33:

The method of any one of Embodiments 26 through 29, wherein growing the electron blocking layer comprises growing the electron blocking layer to have a superlattice structure comprising alternating layers of GaN and Al_eGa_{1-e}N, wherein $0.1 \leq e \leq 0.2$.

Embodiment 34:

The method of any one of Embodiments 26 through 33, further comprising growing an electron stopping layer disposed between the GaN base layer and the active region,

33

wherein the electron stopping layer is at least substantially comprised by $\text{Al}_{st}\text{Ga}_{1-st}\text{N}$, wherein $0.01 \leq st \leq 0.20$.

Embodiment 35:

The method of any one of Embodiments 26 through 34, further comprising growing a strain relief layer disposed between the GaN base layer and the active region, the strain relief layer having a superlattice structure comprising alternating layers of $\text{In}_{sra}\text{Ga}_{1-sra}\text{N}$, wherein $0.01 \leq sra \leq 0.10$, and $\text{In}_{srb}\text{Ga}_{1-srb}\text{N}$, wherein $0.01 \leq srb \leq 0.10$, and wherein sra is greater than srb .

Embodiment 36:

The method of any one of Embodiments 26 through 35, wherein forming the active region further comprises growing one more additional barrier layers comprising GaN disposed between the at least one well layer and the at least one barrier layer.

Embodiment 37:

The method of any one of Embodiments 26 through 36, wherein the GaN base layer, the active region, the electron blocking layer, the p-type bulk layer and the p-type contact layer together define a growth stack exhibiting a percentage strain relaxation of less than 1%.

Embodiment 38:

The method of Embodiment 37, further comprising forming the growth stack to have a critical strain energy of about 2800 (a.u.) or less.

Embodiment 39:

The method of any one of Embodiments 26 through 38, wherein growing the p-type contact layer comprises growing the p-type contact layer to be at least substantially comprised of GaN.

Embodiment 40:

The method of Embodiment 37 or Embodiment 38, further comprising growing the growth stack in a single chemical vapor deposition system at pressures between about 50 and about 500 mTorr.

Embodiment 41:

The method of any one of Embodiments 26 through 40, further comprising growing the p-type $\text{In}_p\text{Ga}_{1-p}\text{N}$ bulk layer in a chamber while flowing trimethylindium (TMI) and triethylgallium (TMG) through the chamber, wherein a flow ratio (%) of the flow rate of the trimethylindium (TMI) to a flow rate of the triethylgallium (TMG) is between about 50% and about 95%.

The example embodiments of the disclosure described above do not limit the scope of the invention, since these embodiments are merely examples of embodiments of the invention, which is defined by the scope of the appended claims and their legal equivalents. Any equivalent embodiments are intended to be within the scope of this invention. Indeed, various modifications of the disclosure, in addition to those shown and described herein, such as alternate useful combinations of the elements described, will become apparent to those skilled in the art from the description. Such modifications and embodiments are also intended to fall within the scope of the appended claims.

What is claimed is:

1. A semiconductor structure, comprising:

a GaN base layer having a polar growth plane with a growth plane lattice parameter of at least about 3.189 Angstroms;

an active region disposed over the base layer, the active region comprising a plurality of layers of InGa_N, the plurality of layers of InGa_N including at least one $\text{In}_w\text{Ga}_{1-w}\text{N}$ well layer,

34

wherein $0.10 \leq w \leq 0.40$, and at least one $\text{In}_b\text{Ga}_{1-b}\text{N}$ barrier layer, wherein $0.01 \leq b \leq 0.10$;

an electron blocking layer disposed on a side of the active region opposite the GaN base layer;

a p-type bulk layer disposed on the electron blocking layer; and

a p-type contact layer disposed on p-type bulk layer.

2. The semiconductor structure of claim 1, further comprising a growth template, the growth template comprising: a support substrate; and

a seed layer disposed on the support substrate, wherein a growth plane of the seed layer is a polar plane with a growth plane lattice parameter of at least about 3.189 Angstroms, wherein the GaN base layer is substantially lattice matched to the growth plane of the seed layer.

3. The semiconductor structure of claim 2, further comprising a spacer layer disposed on the seed layer on a side thereof opposite the GaN base layer.

4. The semiconductor structure of claim 1, further comprising a cap layer disposed between the active region and the electron blocking layer.

5. The semiconductor structure of claim 1, further comprising an electron stopping layer disposed between the GaN base layer and the active region.

6. The semiconductor structure of claim 5, wherein the electron stopping layer has a superlattice structure comprising alternating layers of materials each comprising Ga and N.

7. The semiconductor structure of claim 1, further comprising a strain relief layer disposed between the GaN base layer and the active region, the strain relief layer having a superlattice structure comprising alternating layers of materials each comprising In, Ga, and N.

8. The semiconductor structure of claim 1, wherein the p-type bulk layer comprises a first material comprising In, Ga, and N, and wherein the p-type contact layer comprises a second material comprising Ga and N, the second material having a composition different from a composition of the first material.

9. The semiconductor structure of claim 1, wherein the electron blocking layer has a superlattice structure comprising alternating layers of materials each comprising Ga and N.

10. A light emitting device, comprising:

a GaN base layer having a polar growth plane with a growth plane lattice parameter of at least about 3.189 Angstroms;

an active region disposed over the base layer, the active region comprising a plurality of layers of InGa_N, the plurality of layers of InGa_N including at least one well layer, and at least one barrier layer;

an electron blocking layer disposed over the active region; a p-type bulk layer disposed over the electron blocking layer; and

a p-type contact layer disposed over the p-type bulk layer; wherein a critical strain energy of the light emitting device is about 4500 (a.u.) or less.

11. The light emitting device of claim 10, wherein the GaN base layer, the active region, the electron blocking layer, the p-type bulk layer, and the p-type contact layer define a growth stack exhibiting a percentage strain relaxation of less than 1%.

12. A method of forming a semiconductor structure, comprising:

providing a GaN base layer having a polar growth plane with a growth plane lattice parameter of at least about 3.189 Angstroms;

35

growing a plurality of layers of InGa_N to form an active region over the base layer, growing the plurality of layers of InGa_N comprising:

growing at least one well layer; and

growing at least one barrier layer over the at least one well layer;

growing an electron blocking layer over the active region;

growing a p-type bulk layer over the electron blocking layer; and

growing a p-type contact layer over the p-type bulk layer.

13. The method of claim 12, wherein providing the base Ga_N layer further comprises forming a growth template, forming the growth template comprising:

providing a support substrate; and

bonding a seed layer to the support substrate, wherein a growth plane of the seed layer is a polar plane with a growth plane lattice parameter of at least about 3.189 Angstroms.

14. The method of claim 12, wherein growing the electron blocking layer comprises growing the electron blocking layer to have a superlattice structure comprising alternating layers of materials each comprising Ga and N.

36

15. The method of claim 12, further comprising growing an electron stopping layer disposed between the Ga_N base layer and the active region.

16. The method of claim 12, further comprising growing a strain relief layer disposed between the Ga_N base layer and the active region, the strain relief layer having a superlattice structure comprising alternating layers of materials each comprising In, Ga, and N.

17. The method of claim 12, wherein forming the active region further comprises growing at least one additional barrier layers comprising Ga_N disposed between the at least one well layer and the at least one barrier layer.

18. The method of claim 12, further comprising forming the semiconductor structure to exhibit a percentage strain relaxation of less than 1%.

19. The method of claim 12, further comprising growing the active region in a single chemical vapor deposition system at pressures between about 50 and about 500 mTorr.

20. The method of claim 12, further comprising growing the p-type bulk layer in a chamber while flowing trimethylindium and triethylgallium through the chamber, wherein a flow ratio of the flow rate of the trimethylindium to a flow rate of the triethylgallium is between about 50% and about 95%.
